The day following the operation the patient volunteered the information "I breathe more freely and feel stronger than I have for years." Very soon a remarkable improvement in his disposition was likewise observed, and he began making detailed plans of the work he was going to do following his discharge from the hospital. When last observed, five months later, he had regained his strength but complained of backache after exertion. His appetite was good and he had had no headaches or attacks of weakness. He was eating a normal diet. The sense of heaviness in the epigastrium had disappeared. Dextrose tolerance tests confirmed the disappearance of hypoglycemia (fig. 2). The postoperative blood sugar estimations are given in table 2, and the results of the dextrose tolerance tests in table 3.

COMMENT

The disappointing feature about this case was the character of the tumor. We expected to find a glandu-

lar, secreting growth and found only a calcareous mass, which could not be sectioned. No pancreatic tissue was found by the pathologist. Soft tissue surrounding the stony mass consisted of fat, connective tissue and several small lymph nodes. There seems to be an analogy between adenomas of the pancreas and of the thyroid. Both become calcareous and both may be associated with hyperfunction. We can offer no explanation but submit this report merely as an example of the relief of hypoglycemic symptoms by removal of a calcareous pancreatic tumor.

TORULOSIS IN MAN

REPORT OF A CASE

KENNETH W. TABER, M.D.

PASADENA, CALIF.

Torulae are yeastlike parasitic fungi frequently found in sputum cultures, especially from patients with chronic bronchitis in the tropics.¹ Under proper conditions they become pathogenic. They have been found in every part of the earth where there have been men educated to recognize them. They occur abundantly in nature on trees, fruits, bees, wasp nests and insects and have even been found in canned butter and milk.

Botanically they fall into the genus of *Cryptococcus*, which belongs to the subclass of *Fungi Imperfecti*, the waste basket for all species that have not exhibited a complete life history and many of which have no relation to disease. Torulae are usually round, multiply both in tissues and in cultures by budding, do not form endospores, and are usually red, white or black. Torula histolytica is white.

Although they do not produce mycelia in tissue or in cultures, they do throw out pseudohyphae—projections which may become so long as to dissipate completely the original round shape of the organisms and simulate mycelia—but these do not branch. In contrast to yeasts, torulae ferment sugars little or not at all.

To date there have been less than sixty cases of torula infection in man reported in the entire world. As early as 1901 Bertarelli and Calamida² of Germany recognized that these "yeasts" were the causative factor in many throat and tonsil infections, particularly membranous angina. In 1902 Frothingham³ reported a case of infection of the lung in a horse by a torula.

It was not until 1916, however, that Stoddard and Cutler⁴ accurately described the clinical and pathologic characteristics of torula infection in man for the first time. They reviewed the reported instances of systemic blastomycosis and found four cases presenting sufficient apparent variation in character of the infecting organisms and in the pathologic condition to justify their inclusion in a separate group. These were cases reported by von Hansemann,⁵ Türk⁶ and Rusk.⁷ Stod-

dard and Cutler believe that many torula infections occur which result in recovery without the true nature of the disease being suspected.

Since 1926, cases of torula infection have been reported of the skin,⁸ central nervous system,⁹ lymph glands,¹⁰ tongue,¹¹ knee,¹² nasopharynx,¹³ meninges,⁹ lungs¹⁴ and infections of the entire body.¹⁵

Ten years ago Dr. Ruth Alvarez¹⁶ published an article on red torula infection of the tongue in which she records having found torula agglutinins in the serum of the patients so affected by a complement fixation test, thereby showing a general reaction of the human body toward these organisms. The agglutination tests were negative two months after the disappearance of the tongue lesions.

Early in 1936 Mitchell¹⁷ published an article in which he associated torula infection with Hodgkin's disease. He asserted that the microscopic picture of torula infection is that of Hodgkin's disease and that these two rare diseases appear together much more frequently than may be accounted for by the theory of probability.¹⁸

The infecting organisms usually enter man by way of the respiratory tract, most often affecting the lung, which it may obstruct mechanically or erode gradually without inflammatory reaction. Occasionally they enter the lymphatics or blood stream and then may affect any organ in the body—most commonly the nervous system.

The symptoms are varied, depending on the parts attacked, but are always delayed in appearance owing to an insidious onset. In the lungs the picture may suggest tuberculosis or tumor. A cough develops with little or no fever or night sweats but with some pain in the chest, malaise and loss of weight. Physical examination may disclose no abnormal signs other than a few bronchial or subcrepitant râles. There may be a slight leukocytosis, but the differential blood count varies little from normal. The organisms may be found in the sputum as round fungi or as short, hairlike rods. Roentgenograms usually show some scarring. Microscopically the organisms have been found in the parenchyma of the lung as well as in the bronchioles, which they may obstruct mechanically without toxicity of the patient.

The cerebral symptoms resemble those due to chronic meningitis or tumor. Fever, if present, is of only moderate grade. The white count is not elevated. The spinal fluid has shown increase of polymorphonuclear leukocytes and of lymphocytes and positive protein

Dr. J. F. Kessel and Dr. B. F. Sturdivant were of valuable assistance in providing the laboratory tests.

tests. The organisms may be found in the spinal fluid. The diagnosis may be made by cultures of the spinal fluid on agar or potato at room temperature and by the intraperitoneal inoculation of white mice or rats. The outlook is apparently unfavorable but may be more hopeful than the few reported cases indicate.

The prognosis appears to depend on the virulence of the particular torula involved, on the resistance of the patient and on the tissue involved. As has been said, torulae are frequently found as contaminating microorganisms in sputum cultures. Castellani¹ has isolated them from the sputum of patients in the tropics suffering from chronic bronchitis. These are saprophytic or only semipathogenic. On the other hand, many of the torula infections reported in this country have terminated fatally. Although this is undoubtedly due to the fact that cases not coming to autopsy are not reported for the most part, it nevertheless shows that the virulence of the different torulae varies greatly.

That the prognosis depends on the resistance of the patient is suggested by the fact that the immediate members of the family of patients suffering from torula infection are free from infection by the same organism. That the tissue infected plays a prominent part in the prognosis is proved by the fact that torula infection of the central nervous system ends fatally, while infection of the tongue, lung or skin may end more favorably.

Treatment should include serum from a horse previously inoculated with the torula from the patient to be treated. In the case reported by Alvarez, quinine and neoarsphenamine were being administered for the treatment of chronic malaria at the time the lesion of the tongue was discovered. The lesion began to diminish in size and after about a month of this treatment it was no longer visible. Sheppe,¹⁴ on the other hand, states that arsphenamine is without value in treating torula of the lung and suggests an antituberculosis regimen with large doses of iodides. He suggests tartrates because they have been so effective against leishmaniasis. Gill¹⁵ reported beneficial results in combating Torula histolytica of the blood stream following sinus infection of the head by daily administration of 120 grains (8 Gm.) of potassium iodide internally, 15 grains (1 Gm.) of sodium iodide intravenously and x-ray exposures to the sinuses, while others state that roentgenograms were of no avail in the cases reported by them but on the contrary excited such discomfort that the patients refused further treatment. Until a special torulacide is discovered, I would hesitate to use iodides in torulosis for the same reason that they are not used in tuberculosis. Their use in syphilis is to liberate the infecting organisms in order to facilitate the germicidal medication reaching them.

Early surgical removal of a circumscribed area of torulosis seems as logical to me as the early removal of carcinoma. Surgery is not indicated in torulosis of the central nervous system or in generalized pulmonary torulosis—such as in the case which is about to be reported—any more than surgery would be indicated in generalized carcinomatosis. The removal of a localized lesion either with the cautery or with the radio knife may well be considered as the treatment of choice.

REPORT OF CASE

A white American woman, aged 71, a widow of fourteen years and a semi-invalid for two or three years, complained chiefly of extreme lassitude of several weeks' duration following a chronic cough.

The family history revealed that the father, mother and sister each died with a cough of some years' standing, while but one brother was living and well, at the age of 77.

Her past history was essentially negative except for pneumonia twice about thirty years before and carbuncles on the neck about two years before.

The present illness started with a cough fifty years earlier following her riddance of a sick horse with a "runny" nose, which the patient used to ride in the Middle West. She had had pleurisy from time to time in both sides of the chest but there had been no night sweats or malaise until the past year or two. She had lost considerable strength and weight during the last year, during which the cough, malaise and pleurisy had become progressively worse.

The patient was wrinkled and had a dry skin; she was lying in the semi-Fowler position gasping for breath. Her throat was slightly injected, her chest poorly clothed, with decreased vocal fremitus on the left posteriorly, hyperresonant throughout, with subcrepitan râles over the entire chest. The heart sounds were distant but normal, with a slight enlargement to the left. There were no murmurs. The abdomen and pelvis were essentially normal. Reflexes were active and equal. There were no abnormal signs in the neuromuscular examination.

Sputum tests showed hyaline masses with indefinite radial striations in the fresh preparation. Stained sputum specimens showed many pus cells, a few gram-positive cocci in pairs and short chains and gram-positive "mycelial threads." Sputum cultures showed a profuse growth of salmon pink colonies on agar with a shiny surface identified as a pigmented torula or *Cryptococcus Kützing*. It is similar in cultural characteristics and appearance to *Cryptococcus pararoseus*, described by Castellani in 1926.

Two monkeys were inoculated with the same organism and killed for examination at the end of three months. This examination proved to be negative, which may indicate that the torula was nonpathogenic but, on the other hand, may indicate that the resistance of the monkeys to this particular organism was greater than that of the patient who died from it.

Roentgenograms of the lung showed thickening of the linear markings throughout with some parenchymal lesions in the right upper lobe and about the lung roots in both bases.

The urine showed a heavy trace of albumin with occasional granular casts, frequent epithelial, pus and blood cells, a few bacteria, and numerous mucous shreds. The blood counts were high, with 97 per cent hemoglobin, a color index of 88, 5,500,000 red blood cells and 15,400 white blood cells with 11 per cent small lymphocytes, 2 per cent large lymphocytes, 8 per cent transitional cells, 77 per cent polymorphonuclear neutrophils and 2 per cent staff cells.

The course was rapidly down-hill for four days, ending in a toxic and respiratory death, treatment having been symptomatic.

At autopsy, in addition to the usual manifestations of a cardiovascular-renal syndrome, which would be expected in a woman of 71, were found a right and a left chronic pleuritis with adhesions, a small cavity of the left upper lobe of the lung, healed tuberculous lesions of the right and left apices, abdominal adhesions, and mycotic bronchitis. In cross section the lung seemed filled throughout with a thick tenacious mucopurulent material, yellow with a slightly pinkish tint. Microscopic examination of the lung tissue showed round cell infiltration with areas of edema and interstitial fibrosis. The patient obviously died from the effects of a microscopic parasite in the bronchioles.

CONCLUSION

Whether the occasional pathogenesis of torulae depends on occasional variations in their own virulence, on the hypersensitivity, or on the lowered resistance of the persons affected is not yet proved. But it would appear from the facts in hand that both factors play a part. With the further development and greater popularity of surgery there is hope for more frequent and correct diagnoses if not for a greater percentage of cures.

THE TREATMENT OF MENINGOCOCCIC
MENINGITIS WITH SULFANILAMIDE

PRELIMINARY REPORT

FRANCIS F. SCHWENTKER, M.D.

SIDNEY GELMAN, M.D.

AND

PERRIN H. LONG, M.D.

BALTIMORE

A number of investigators have pointed out the therapeutic value of sulfanilamide (para-amino-benzene-sulfonamide) in infections due to the beta-hemolytic streptococcus. A review of this work will be found in

Read in part before the Medical Society of the County of Kings, Brooklyn, Feb. 16, 1937.

From the Sydenham Hospital, Baltimore City Health Department and the Department of Medicine, Johns Hopkins Hospital.

the recent article of Long and Bliss.¹ Buttle and his co-workers² and Proom³ have also demonstrated protective and curative properties for the drug against meningococcic infections in mice. This paper will report the preliminary observations on the use of sulfanilamide in the treatment of ten cases of meningococcic meningitis and one of septicemia only. The ages of the patients ranged from 1 to 34 years. After the first two patients had been treated, the drug was used in every case admitted for meningococcic infection. There was therefore no selection of cases; they ranged in severity from moderate to severe illness.

* Sulfanilamide was used in 0.8 per cent solution in physiologic solution of sodium chloride.

METHOD OF TREATMENT

Within the limitations of individual need, all patients were treated in the same manner, by subcutaneous and intraspinal injection of the drug. The solution was prepared in the following manner: A measured volume of sterile physiologic solution of sodium chloride was heated in a flask. When the saline began to boil, the flask was removed from the flame and a weighed amount of sulfanilamide was added in quantity to make an 0.8 per cent solution of the drug. The mixture was cooled to about 37 C. and injected immediately.

After a diagnosis of meningococcic meningitis had been made, sulfanilamide solution was injected intraspinally into the patient in amounts varying from 10 to 30 cc. As a general rule the amount injected was from 5 to 10 cc. less than the volume of spinal fluid removed. A larger amount of the solution was also given subcutaneously, approximately 100 cc. being injected for each 40 pounds (18 Kg.) of body weight. Both the intraspinal and subcutaneous treatments were repeated every twelve hours for the first two days and once each day thereafter until definite improvement was evident. In some instances subcutaneous injection of the drug was continued for several days longer than the intraspinal treatment.

RESULTS

The results are summarized in the accompanying table. Certain interesting facts are evident. In some cases the cell count of the spinal fluid fell rapidly and progressively. In others the count remained elevated for several days, then decreased precipitously. Culture of the spinal fluid of a number of patients was sterile after the first treatment; for others several treatments were required, but in no case was the organism recovered longer than three days after instigation of treatment. The speed of clinical improvement also varied from rapid to a more protracted return to normal. In two patients transient arthritis developed. There was one death. This patient (E. M., patient 9) was desperately ill at the time of admission, showed symptoms of encephalitic involvement and died of pneumonia on the fifth day despite the fact that the spinal fluid had been sterile for three days and the cell count was only 158 on the day of death.

No untoward effects following the use of sulfanilamide have been noted. When given subcutaneously the solution was rapidly absorbed and gave rise to no more tenderness or reaction at the site of injection than that which follows the subcutaneous administration of physiologic solution of sodium chloride. No signs of local or systemic reaction followed intrathecal injection. Although transient methemoglobinemia, sulfhemoglobinemia, mild acidosis and morbilliform rash have each occasionally occurred in patients treated with sulfanilamide for streptococcic infections, none of these conditions have been noted in the patients in this series.

COMMENT

There are obviously too few cases in this preliminary series to permit any very definite conclusions. The therapeutic response of the patients, however, to treatment with sulfanilamide seems quite comparable to that which usually follows treatment with specific antiserum. The mortality (9 per cent) in such a small series could have no real significance. On the other hand it is so much less than one would expect in cases treated only by repeated subarachnoid drainage that one cannot

escape the impression that sulfanilamide has some definite value in the treatment of meningococcic infections. Only with more widespread experience can the decision be reached whether the drug has sufficient therapeutic value to supplant antimeningococcus serum or whether it should be used only as an adjunct to serum treatment. One definite value of sulfanilamide over antimeningococcus serum is the absence of any irritative effect due to foreign protein. Certainly this property of serum, especially when it is injected into the subarachnoid space, gives rise to serious complications.

CONCLUSIONS

Sulfanilamide has been used in the treatment of ten patients with meningococcic meningitis and of one with septicemia only. The response to treatment was good in all the patients and seemed quite comparable to that caused by the specific antiserum.

Clinical Notes, Suggestions and New Instruments

ESOPHAGEAL OBSTRUCTION FROM A HYGROSCOPIC GUM LAXATIVE (SARAKA)

JOSEPH L. GOLDMAN, M.D., NEW YORK

Although intestinal obstruction from hygroscopic gum laxatives is a condition that has been observed many times, no record of esophageal obstruction from such a cause has been found in the recent literature. The widespread use of gum laxatives and the potential seriousness of esophageal obstruction caused by such a preparation warrant the report of the following case:

G. S., a man, aged 47, had been suffering from constipation for many years. He had found Saraka a beneficial laxative and had been taking this proprietary drug from three to four times a week for seven years. The company that markets the preparation directs that from 1 to 2 drachms of Saraka be taken after meals and washed down with sufficient water, or that the laxative be ingested with stewed fruit. The patient, however, was accustomed to take a much larger quantity of the Saraka than directed. He would place a handful of the laxative in his mouth and then swallow the substance with water.

According to the Council on Pharmacy and Chemistry of the American Medical Association, Saraka owes its activity to two elements, an indigestible gum called bassorin, which has the ability, like agar, of absorbing moisture and increasing greatly in bulk, and the drug frangula, which is practically identical with cascara.

On the evening of July 1, 1935, the patient in his usual manner placed a large handful of Saraka in his mouth and proceeded to wash this down with water. While drinking the water, he experienced laryngeal irritation and developed an attack of paroxysmal cough. After the cough had ceased he attempted to drink more water, but this precipitated violent retching and regurgitation of the fluid and particles of the Saraka. He soon began to experience a substernal ache, which became very severe during the night. It felt to him as though "tissues were tearing." Any further swallowing of water caused explosive reactions of retching and regurgitation, and marked pain. The patient could not assume a recumbent or semirecumbent position without increasing the pain considerably and experiencing a constricting and choking sensation.

The following morning, while traveling from his home in the country to his physician in New York, the late Dr. Herman Mond, the patient had to sit in a doubled-up position in order to tolerate the pain and distress. Dr. Mond made a fluoroscopic study of the esophagus with barium sulfate. He noted that the fluid stopped abruptly and completely at a distance of two-

From the Department of Laryngology of the Mount Sinai Hospital.

thirds the length of the esophagus and that the lower portion of the esophagus proximal to the obstruction was quite distended. I was consulted and immediately performed an esophagoscopy.

On esophagoscopy, the lower third of the esophagus was found impacted with a gelatinous, resinous substance, which had dilated the esophagus to twice its normal width. The material was in a solid mass and could not be aspirated. The mass was broken up by a punch forceps into small pieces, which were removed by forceps, suction and moist cotton swabs. No evidence of any neoplasm or cardiospasm was noted. The patient was not permitted to swallow any fluid until the following morning, at which time this was accomplished without any discomfort.

It is now a year and a half since the accident occurred, and the patient has experienced no esophageal symptoms of any kind. During this period he has been in good health.

The condition presented in this communication is very rare and may be attributed to carelessness on the part of the patient. It emphasizes a possible danger of the injudicious ingestion of hygroscopic gum laxatives and the importance of following exact directions. An esophageal impaction of this type may result in a tear of the esophageal wall from extreme dilatation or in a perforation from difficult instrumentation.

12 East Eighty-Sixth Street.

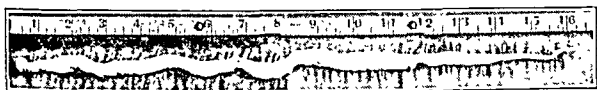

MEDICAL CURIOSITIES

P. T. GEYERMAN, M.D., HOT SPRINGS, S. D.

I realize that the relating of this case is of no particular scientific value, yet it must be of such rare occurrence that a brief report should be of interest to the medical profession. As far as I know, no similar case has ever been reported.

H. D., a man aged 44, single, a rancher, was referred to me by his family physician July 7, 1931, with a diagnosis of having a snake in the bladder. I obtained the following history from the patient: He had had bladder symptoms for about fifteen years, consisting of frequency and dysuria. There was nothing else in the urinary or general history of any importance.

Two days previously he had passed a small decapitated snake into the urethra and while doing this, he stated, it slipped from his grasp and passed into the bladder. The patient had a hypospadias but no evidence of any further trouble. General physical examination was negative. The patient was suffering from intense bladder pain and frequency of urination. Exam-

Length of snake taken from bladder of patient.

ination of the urine showed a large amount of pus and some blood cells and four plus albumin. The patient was very reticent about answering questions but on being questioned closely admitted having inserted the snake into the bladder, believing that it might give him relief from the bladder symptoms which he had complained of for a number of years.

A roentgenogram of the bladder revealed rather distinctly the vertebrae of the reptile. The next morning he was prepared for a probable cystotomy, with the thought in mind, however, that the snake might be removed through the cystoscope. He was given a spinal anesthetic and the cystoscope was passed. The cystitis was so intense that it required a good deal of irrigation before a clear cystoscopic view could be obtained. However, the snake soon came into view and the tail could be seen waving in the fluid. This was grasped by forceps and pulled into the cystoscope and held fast. As the snake was too large to be pulled through the instrument, the instrument and snake were pulled out together. The snake was what is commonly known as a "garter snake" and measured 18 inches (45.7 cm.) in length. The patient made an uneventful recovery and has had no further trouble.

This case is probably of more interest from the standpoint of sexual perversion than from any other angle.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
HOWARD A. CARTER, Secretary.

STATUS OF DIATHERMY AND SHORT WAVE DIATHERMY

Medical diathermy is the use, for therapeutic purposes, of heat generated in the body tissues by high frequency currents, insufficient in amount, however, to produce temperatures high enough to destroy the tissues or impair their vitality. These currents are applied locally by three methods: (1) with contact metal electrode, (2) with a high frequency alternating electric field electrode or (3) with a high frequency electromagnetic field coil.

The first method is the one by which conventional diathermy is applied. The frequency of oscillations is usually from one-half million to two million cycles per second.

The second method for the local application of diathermy currents is the use of a high frequency electric field. The frequency of oscillations may be from ten million to a hundred million cycles per second. The electrodes are not in contact with the skin, as conventional medical diathermy electrodes are. These short wave diathermy electrodes are made of metal insulated by rubber or felt. The electrodes are so encased as to prevent arcing from the metal to the skin. When applied they are usually separated from the skin by a half-inch layer of dry felt or towels. The towel or felt is placed between the electrodes and the skin to prevent the accumulation of surface moisture into small conducting areas, which might produce burns.

The methods of applying the electric field that have been accepted by the Council on Physical Therapy are those making use of double cuff electrodes and air-spaced electrodes. Ordinarily, cuffs are placed so that the part to be treated is midway between them. The double cuff method, according to the experiments submitted to the Council, always showed superior heating of the deep tissues of the human thigh over the pad electrode method. In fact, this mode of application of electric field electrodes was the only one in these experiments that insured better heating of the deep tissues than was obtained with conventional diathermy employing contact electrodes applied opposite each other. The Council has not accepted pad electrodes for use with the electric field method. Physicians buying short wave diathermy machines should consult the published acceptance of these machines regarding their relative efficiency, and furnished accessories.

Air spaced electrodes for use with the electric field have been accepted by the Council for certain techniques; for example, when placed on the same side of the part to be treated, and in some instances when applied on either side of the part.

The third method of heating tissues by high frequency currents is by electromagnetic fields, or so-called electromagnetic induction. In this method the current is carried to the patient through a flexible, heavily insulated cable, which is wound around the part to be treated in the form of coils or loops. The part under treatment is separated from the coil or loop by a towel for the reasons mentioned.

Burns may occur with any method of applying short wave medical diathermy as well as with the contact metal electrodes of conventional diathermy. The manufacturers of short wave machines claimed in their early advertising matter that burns were impossible. The Council was unable to accept these claims, since evidence was available that burns did occur.

To avoid burns, several layers of absorbent material are placed between the electrodes or coils and the skin, to absorb perspiration. The collection of moisture between the skin and the electrodes would cause a concentration of energy at these points, and burns would result if the patient did not inform the operator that there was a burning sensation. The patients who have been burned have had a distinct sensation of burning. This would be expected, as the subcutaneous tissues are always warmer than the deeper tissues directly under the electrodes. Such burns resemble those obtained by electrocoagulation and they are slow in healing.

The effects of common electric currents when applied to the body tissues may be thermal, chemical or mechanical in nature, depending on the physical characteristics of the current. High frequency currents apparently avoid the mechanical and chemical effects but display the ability to heat the body tissues through which they pass. At the present time it is believed that the local physiologic effects of the three methods of applying high frequency currents aforementioned are limited to the effects of the heat produced.

So far as competent investigators have been able to determine, there is no demonstrable, selective thermal action, or specific biologic or bactericidal actions in vivo that may be attributed to short wave diathermy. To date, the effects produced can be explained only on the basis of the generation of heat.

The conditions in which heat is a beneficial adjunct in treatment are to be found in the Handbook of Physical Therapy published by the American Medical Association.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

DIGITALIS (See New and Nonofficial Remedies, 1936, p. 168).

The following dosage forms have been accepted:

Tablets Digitalis Duo-Test McNeil, 1/2 grain: Each tablet contains 1/2 cat unit.

Tablets Digitalis Duo-Test McNeil, 1 grain: Each tablet contains 1/2 cat unit and is dispensed in plain and enteric coated tablets. The enteric coated tablets are first coated with a wax-salol mixture and then sugar coated green.

Tablets Digitalis Duo-Test McNeil, 1 1/2 grains: Each tablet contains 1 cat unit and is dispensed in plain and enteric coated tablets. The enteric coated tablets are first coated with a wax-salol mixture and then sugar coated green.

Capsules Digitalis Duo-Test McNeil, 1 1/2 grains: Each capsule contains 1 cat unit and is dispensed in black capsules.

Prepared by the McNeil Laboratories, Inc., Philadelphia.

DIPHThERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1936, p. 392).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

Diphtheria Toxoid, Alum Precipitated.—Prepared by treating diphtheria toxoid with a solution of alum until complete precipitation is produced. The precipitate is thoroughly washed and then suspended in physiologic solution of sodium chloride. The product is tested for antigenic potency according to the method prescribed by the National Institute of Health: guinea-pigs weighing 500 Gm., given one human dose, must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood. Ortho-chloro-mercuri phenol 1:20,000 is used as the preservative.

Marketed in packages of one 0.5 cc. vial and one 1 cc. vial; in packages of ten 0.5 cc. vials and ten 1 cc. vials; and in packages of one 5 cc. vial and one 10 cc. vial.

AMINOPYRINE (See New and Nonofficial Remedies, 1936, p. 340).

Aminopyrine—"National."—A brand of aminopyrine—U. S. P.

Manufactured by the National Aniline and Chemical Co., New York.
Aminopyrine Tablets, 5 grains.

COD LIVER OIL (See New and Nonofficial Remedies, 1936, p. 450).

Möller Plain Cod Liver Oil Standardized.—It has a vitamin A potency of not less than 1,000 units (U. S. P.) per gram and a vitamin D potency of not less than 150 units (U. S. P.) per gram.

Dosage.—For adults, 4 cc. (60 minims) to 15 cc. (225 minims) three times a day; for children, 2 cc. (30 minims) to 4 cc. (60 minims) three times a day.

Manufactured by Peter Möller, A/S, Oslo, Norway; distributed in the United States by Schieffelin & Co., New York. No U. S. patent or trademark.

Möller plain cod liver oil standardized complies with the U. S. P. standards for cod liver oil. In addition it is required to have a vitamin A potency of not less than 1,000 units per gram and a vitamin D potency of not less than 150 units per gram.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

BLUE LABEL TOMATO JUICE

Manufacturer.—Curtice Brothers Company, Inc., Rochester, N. Y.

Description.—Canned tomato juice seasoned with salt, retaining in high degree the natural vitamins.

Manufacture.—Varieties of ripe tomatoes meeting specific requirements are inspected, mechanically washed, scalded, hand trimmed and cored. The juice is mechanically expressed, heated, and seeds and skins are removed. The juice is seasoned with salt, filled into cans at 82 C. and processed for twenty minutes at 82 to 85 C.

Analysis (submitted by manufacturer).—Moisture 92.9%, total solids 7.1%, ash 0.9%, sodium chloride (NaCl) 0.6%, fat (ether extract) trace, protein (N \times 6.25) 1.1%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 4.9% and total acid as citric 0.5%.

Calories.—0.2 per gram; 6 per ounce.

Vitamins.—Approximately 74 International units vitamin C per fluidounce.

SEXTON BRAND RED PITTED CHERRIES, JUICE PACKED

Manufacturer.—John Sexton & Company, Chicago.

Description.—Canned cherries, packed in juice.

Manufacture.—Cherries, picked without stems, are washed, inspected, mechanically pitted, automatically filled into cans and weighed. The cans are filled with juice, exhausted, sealed and processed.

Analysis (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 87.4%, total solids 12.6%, ash 0.48%, fat (ether extract) 1.0%, protein (N \times 6.25) 1.0%, crude fiber 0.14%, carbohydrates other than crude fiber (by difference) 10.0%.

Calories.—0.53 per gram; 15 per ounce.

Claims of Manufacturer.—For diets in which sweetened fruit is proscribed.

SEXTON BRAND FRESH GREEN ASPARAGUS, WATER PACKED

Manufacturer.—John Sexton & Company, Chicago.

Description.—Canned green asparagus, packed in water.

Manufacture.—Green asparagus, harvested when spears are from 5 to 8 inches above ground, is washed, sorted for quality and size, cut uniformly, again washed, sorted, mechanically cut, washed again in cold, hot and cold waters, again inspected and placed in cans. The cans are inspected for grading, counts and proper quality, filled with water, exhausted, sealed and processed.

Analysis (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 93.7%, total solids 6.3%, ash 0.49%, fat (ether extract) 0.2%, protein (N \times 6.25) 2.3%, crude fiber 0.41%, carbohydrates other than crude fiber (by difference) 2.9%.

Calories.—0.3 per gram; 9 per ounce.

Claims of Manufacturer.—Choice quality asparagus packed in water without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

NORRIS BRAND EVAPORATED MILK

Distributor.—Schuylkill Valley Grocery Co., Inc., Norris-town, Pa.

Packer.—Amboy Milk Products Company, Amboy, Ill.

Description.—Canned, evaporated milk; the same as Amboy Brand Unsweetened Evaporated Sterilized Milk (THE JOURNAL, May 7, 1932, p. 1655).

MEDICAL LICENSURE STATISTICS FOR 1936

ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The Council on Medical Education and Hospitals presents herewith medical licensure statistics for the thirty-fifth consecutive year. The report covers the year 1936 and deals with statistics regarding (a) medical licensing boards of the United States, including the District of Columbia and territories and possessions of the United States, (b) boards of examiners in the basic sciences, and (c) the National Board of Medical Examiners.

Official reports have been contributed by the officers of the medical licensing boards of all states, the District of Columbia, Alaska, the Canal Zone, Hawaii, Puerto Rico and the Virgin Islands; the homeopathic examining boards of Arkansas, Connecticut, Delaware, Louisiana and Maryland; the eclectic examining board in Arkansas; the ten basic science examining boards in operation (Arizona, Arkansas, Connecticut, District of Columbia, Iowa, Minnesota, Nebraska, Oregon, Washington and Wisconsin), and the National Board of Medical Examiners. The homeopathic boards of Arkansas and Louisiana and the eclectic board in Arkansas did not license any one during the year. Acknowledgment is tendered the officers of the foregoing boards for their ready cooperation and the complete reports they have furnished.

Reports of all examinations and those licensed without examination are carefully compared with lists of graduates furnished by medical school officials, so that errors in regard to names of applicants, the medical schools or the years of graduation are promptly corrected. In the occasional instance in which the applicant has not graduated or there is a record of irregularity, the state board is promptly notified. Credentials of physicians coming from abroad are verified by direct correspondence with the foreign medical schools. Thus the statements regarding the medical education and licensure of all physicians are known to be accurate.

The data supplied were also entered in the biographic file of physicians and others maintained by the American Medical Association, thus serving a dual purpose. About thirty licensing boards obtain from the American Medical Association verification of biographic data and other claims before granting a license or permission to take the licensing examination. This service is available to all licensing boards.

The tables showing medical licensing boards results include figures regarding the number of candidates for medical licensure in 1936, the number licensed and the number added to the profession.

LICENTIATES

The first table contains figures on the number of licenses issued in the various states, territories and possessions during the year. There were 9,008 licenses issued, 6,263 on the basis of examination and 2,745 by endorsement of credentials. In several states (table 9) the internship is a requisite for practice, but a physician is permitted to take the examination and if successful his license is withheld until completion of his internship. Licenses are also withheld for lack of citizenship or minor technicalities. The figures, therefore, for those

licensed after examination include many who were examined in 1935 and even a few in previous years. New York issued the largest number of licenses, 1,517, Pennsylvania issued 629, Illinois 577, California 567, Ohio 464, Massachusetts 352 and Texas 325. A comparison with similar figures for 1935 indicates that in New York 243 more licenses were issued, in Pennsylvania 104, Illinois 52, California 95, Ohio 48, Massachusetts 89 and Texas 6.

Totals.....	6,263	2,745	9,008

* Alaska, Canal Zone, Hawaii, Puerto Rico, and Virgin Islands.

Six states licensed between 200 and 300 licentiates and thirteen between 100 and 200. Twenty-two states, the District of Columbia, Alaska, Canal Zone, Hawaii, Puerto Rico and the Virgin Islands licensed less than 100. None were licensed by examination in Nevada. Florida grants licenses only on the basis of examination. Massachusetts and Rhode Island have no reciprocity privileges but endorse diplomates of the National Board of Medical Examiners. The total number licensed, 9,008, was 1,104 more than in 1935. Licensed on the basis of examination, the figure increased 549 and those licensed without examination increased 555. This figure, however, does not represent 9,008 individuals.

(CONTINUED FROM PAGE 1411)

since several have been licensed in more than one state during the year. Nor does it represent additions to the medical profession at large, since the 2,745 licensed by endorsement, with the exception of those licensed in New York on the basis of foreign credentials, have migrated from other states. Table 5 shows how many of those licensed were never before registered and therefore represent the number added to the medical profession.

TOTAL EXAMINED

Figures referring to those examined for medical licensure by individual states throughout the year, giving the number who passed and failed in each state, are included in table 2. There were 6,906 examined, of whom 6,210 passed and 696 failed, representing graduates from the sixty-seven approved four year medical schools in the United States and nine in Canada, seventy-three medical schools of other countries, eighteen medical schools now extinct, ten unapproved institutions and several osteopathic colleges. Five undergraduates were examined. Osteopaths granted the privilege to practice medicine, surgery or both by the medical board are included in these statistics. There were 5,705 graduates of approved medical schools in the United States examined, of whom 4.3 per cent failed; 128 graduates of approved Canadian medical schools, 12.5 per cent of whom failed; 588 graduates of schools outside the United States and Canada with 35.4 per cent failures; 25 who graduated from schools now extinct with 48.0 per cent of failures, and 460 from unapproved and osteopathic schools, of whom 47.0 per cent failed. These 460 candidates represented 107 graduates of osteopathic schools, of whom 43 passed and 64 failed, 59.8 per cent; 348 graduates of unapproved schools, of whom 201 passed and 147, 42.2 per cent, failed and five undergraduates examined, all failed.

Four of these undergraduates were permitted to be examined in Mississippi by special acts of the legislature and the fifth was examined in New York. This individual claimed graduation from a foreign medical school but his claims have not been substantiated by official correspondence. Graduates of osteopathic schools were examined in Colorado, Connecticut, Massachusetts, New Jersey, Texas and Wisconsin, while graduates of unapproved schools were examined in Arizona, Florida, Illinois, Massachusetts, Missouri, New Jersey, New Mexico, North Carolina, Ohio and Hawaii. Illinois registered eighty-four, Massachusetts seventy-seven and Ohio thirty-one practitioners of the latter group.

The 6,906 examined do not represent individuals, since a candidate might take the examination in more than one state and would be counted in each state. This applies to those who pass or fail, or those who fail and later pass in one or more states or pass in one state and later within the same year fail elsewhere. However, if a physician fails more than once in a given state within the year he is counted in that state only once as a failure.

Three of the five homeopathic boards in existence, Connecticut, Delaware and Maryland, examined twenty-eight candidates, all of whom passed. The homeopathic boards of Arkansas and Louisiana did not license any one during the year. The one eclectic board in existence in Arkansas did not examine any candidates.

The largest number of graduates of any one school examined was 193 from Northwestern University Medical School, who were examined by twenty-eight licensing boards. There were 190 graduates of Rush Medical College examined by twenty-seven boards. The next highest number of graduates of any one school was Jefferson Medical College, which had 185 graduates examined by twenty-three boards. The

P = Passed; F = Failed.

* Alaska, Hawaii, Puerto Rico.

New York Medical College and Flower Hospital and Georgetown University School of Medicine had the highest percentage of failures in the United States, 22.5 and 21.8, respectively. Graduates of Harvard University Medical School were examined by twenty-nine boards, Northwestern University Medical School by twenty-eight, Rush Medical College by twenty-seven, the University of Pennsylvania School of Medicine by twenty-five, Jefferson Medical College by twenty-three and Creighton University School of Medicine by twenty-one boards. From those statistics it might be inferred that these schools educate more non-residents than do other schools. Graduates of Albany Medical College (twenty-nine) were examined by two state boards, one of which was New York, where the college is located. Graduates of the University of California Medical School (fifty-nine) were examined in three states.

Canadian graduates took the test in twenty-five states and Puerto Rico. The greatest number, fifty-four, represented McGill University Faculty of Medicine, who were examined in seventeen states; twenty-two graduates of the University of Toronto Faculty of Medicine were examined in twelve states, and twenty graduates of Queen's University Faculty of Medicine were examined in nine states. The six graduates of the University of Montreal Faculty of Medicine were examined in six states. The highest percentage of failures was 50, representing, respectively, Laval University Faculty of Medicine and the University of Montreal Faculty of Medicine.

The following fourteen schools had no failures before state licensing boards: University of Southern California School of Medicine, Yale University School of Medicine, State University of Iowa College of Medicine, Louisiana State University Medical Center, Wayne University College of Medicine, Duke Univer-

sity School of Medicine, Ohio State University College of Medicine, University of Oklahoma School of Medicine, University of Oregon Medical School, Vanderbilt University School of Medicine, University of Wisconsin Medical School, Dalhousie University Faculty of Medicine, University of Alberta Faculty of Medicine and the University of Manitoba Faculty of Medicine.

In 1935, 6,428 were examined, of whom 5,843 passed and 9.1 per cent failed, as compared with 6,906 examined in 1936, of whom 6,210 passed and 10.1 per cent failed. There were 478 more examined than in 1935, of whom 367 passed and 111 failed.

REGISTRATION BY RECIPROCITY AND ENDORSEMENT

The number of physicians granted licenses to practice medicine and surgery without examination in the states and territories are given in table 4. These individuals presented licenses from other states, Canada and foreign countries, the certificate of the National Board of Medical Examiners, one of the government services, or other credentials.

Definite reciprocal agreements exist in many of the states, but twenty-eight states and the District of Columbia register without examination licentiates who present credentials which correspond to those required by their respective states at the time such licenses were issued. These are:

Alabama	Michigan	Oklahoma
Arizona	Minnesota	Oregon

TABLE 4.—*Credentials Presented by Physicians for Licensure by Reciprocity and Endorsement—1936*[illegible]

* Alaska, Canal Zone, Hawaii, Puerto Rico, Virgin Islands.

(CONTINUED FROM PAGE 1415)

date of filing an application for a California license and the date of the original license), Connecticut, Illinois, Maryland, Minnesota, Nevada, North Carolina, South Dakota and Washington require a practical or oral examination of reciprocity or endorsement applicants before a license is granted by this method. Applicants in Idaho are required to pass either a written or an oral examination in medical jurisprudence as pertaining to practice in that state. Those desiring licenses in Arizona, Arkansas, Connecticut, the District of Columbia, Iowa, Minnesota, Nebraska, Oregon, Washington and Wisconsin are required to obtain a certificate from the board of examiners in the basic sciences before being eligible for licensure.

Florida, Massachusetts and Rhode Island do not have reciprocal or endorsement arrangements with any state. Massachusetts and Rhode Island, however, will register diplomates of the National Board of Medical Examiners by endorsement. Rhode Island requires such diplomates to pass an oral examination.

New York granted the greatest number of licenses by endorsement in 1936 (585), California was second with 197, Ohio third with 140, New Jersey fourth with 129, Texas fifth with 115 and Illinois sixth with 108. All other states licensed fewer than 100. The largest group representing the same type of credentials were the 540 diplomates of the National Board of Medical Examiners; the next greatest number (216) were from Canadian and foreign countries; Illinois was third with 162, Missouri fourth with 146, and Maryland fifth with 127. Only 122 New York licenses were endorsed during the year, while 585 were licensed in New York on the basis of credentials. Of the latter, 216 were registered on the basis of Canadian and foreign licenses or diplomas giving the right to practice in the country in which issued. However, at a meeting of the New York State Board of Regents, Sept. 21, 1936, it was voted that on applications filed after October 15 no license issued by a legally constituted board of examiners in any foreign country will be endorsed until the applicant shall pass the licensing examination prescribed by law or regents' rule.

Nine physicians were licensed on the basis of Canadian provincial credentials, all in New York. Credentials were presented from Alberta, British Columbia and Nova Scotia, one each, and six were from Ontario. New York was the only state in which physicians were registered by endorsement of European credentials. There were 207 so licensed, representing the following countries: Australia one, Austria eleven, Belgium one, Dominican Republic one, England one, France one, Great Britain one, Germany 182, Holland one, Hungary two, Italy two, Russia two and Switzerland one. Two physicians were registered in California by the endorsement of certificates from Hawaii and three in New York on the basis of licenses issued in Puerto Rico.

Not included in the table are forty-three osteopaths licensed by the board of medical examiners in three states; namely, thirty-four granted the right to practice medicine and surgery in Texas, five licensed to practice osteopathy and surgery in Wisconsin, and four also licensed to practice osteopathy and surgery in Wyoming.

Diplomates of the National Board of Medical Examiners were registered in forty-one states, the District of Columbia, Alaska, Hawaii and Puerto Rico.

Missouri licentiates (146) were registered in thirty-four states, while the state that had the highest number of its licenses endorsed, Illinois had its 162 licentiates registered in thirty-three states, twenty-five of whom went to Michigan, twenty-one to California, seventeen to Wisconsin and thirteen to Texas. Maryland had the greatest number of its licentiates registered in any one state, fifty-five, who were given the right to practice in New York; fifty-one licentiates of New York went to New Jersey; Arizona, Connecticut, Delaware, District of Columbia, Florida, Montana, Nevada, New Hampshire, New Mexico, North Dakota, Rhode Island,

* Hawaii, Puerto Rico.

South Dakota, Vermont, West Virginia, Wyoming, Hawaii and Puerto Rico had less than ten of their licentiates endorsed to other states and Idaho had none.

A total of 2,702 physicians secured licenses by this method during 1936.

In table 3, the 2,702 physicians licensed by reciprocity and endorsement and, in addition, forty-three osteopaths so licensed, are recorded by school of graduation and state or territory where licensed. All the existing United States four-year medical schools and eight medical schools of Canada were represented. The largest number of graduates of any one school were from Harvard University Medical School, 116; Washington University School of Medicine had 79 licensed by this method; St. Louis University School of Medicine 77, Rush Medical College 73 and Johns Hopkins

University School of Medicine had 70. Graduates of 44 foreign medical faculties and five licensing corporations of England and Scotland, 36 extinct medical schools and four unapproved institutions, and several

graduates of foreign medical faculties registered, 84 from extinct medical schools and 62 graduates of unapproved schools.

CANDIDATES ADDED TO THE PROFESSION

The number of licentiatees added to the profession during 1936 are given in table 5. The figures represent candidates examined in 1936 and licensed; also those examined in previous years whose licenses were withheld and issued in 1936, those certified on the basis of the certificate of the National Board of Medical Examiners, government services, Canadian and foreign credentials, and miscellaneous. In the main they represent recent graduates. Altogether, 6,166 were added to the profession, as contrasted with approximately 4,000, the number removed by death in 1936. These figures indicate that at least 1,500 have been added to the already overcrowded medical profession. It is assumed that by far the great majority of those licensed are in practice. It is interesting to note that, of 9,008 licenses issued throughout the year, 6,166, 68.5 per cent, are actual additions to the medical profession.

TABLE 7.—*State Requirements of Preliminary Training*

Two Years of College		
Alabama	Maine	Oregon
Arizona	Maryland	Rhode Island
Arkansas	Michigan	South Carolina
Colorado	Minnesota	South Dakota
District of Columbia	Mississippi	Tennessee
Florida	Montana	Texas
Georgia	Nevada	Utah
Idaho	New Hampshire	Vermont
Illinois	New Jersey	Virginia
Indiana	New Mexico	Washington
Iowa	New York	West Virginia
Kansas	North Carolina	Wisconsin
Kentucky	North Dakota	Wyoming
Louisiana	Oklahoma	
One Year of College		
California	Connecticut	Pennsylvania
High School Graduation or its Equivalent		
Delaware	Missouri	Ohio
Massachusetts	Nebraska	

The largest number added to the profession was in New York, 1,200; Pennsylvania added 496 and Illinois 463, while Nevada added one. Of the number of licentiatees representing additions to the medical profession during 1936, 5,538 secured this privilege by examination and 628 by the endorsement of credentials, the greatest majority of which (324) were licensed in New York State and represent graduates of foreign medical schools licensed on the basis of their credentials and diplomates of the National Board of Medical Examiners. In 1935 there were 5,096 added by means of examination and 411 by endorsement of credentials, a total of 5,507. In 1936 there were 659 more added than in 1935. No additions were made to the physician population of Alaska, Canal Zone or the Virgin Islands, while nineteen were added in Hawaii and Puerto Rico. Table 6 records the licentiatees representing additions to the medical profession, by sections of the country. The largest number (1,850) was added to the Middle Atlantic group and the fewest number to the Mountain division, 144.

STATE REQUIREMENTS OF PRELIMINARY TRAINING

The minimum requirement of preliminary education exacted by the Council on Medical Education and Hospitals since 1918 has been two years of college work. There are still eight states, however, which have not

osteopathic schools were licensed without examination. Thirty-four osteopaths were granted the right to practice medicine and surgery in Texas and five and four, respectively, permitted the privilege of practicing surgery in Wisconsin and Wyoming. There were 264

revised or amended their statutes to conform with this prerequisite, although these states with possibly one or two exceptions do not license other than graduates of approved schools. Table 7 records the premedical training required in each state.

REQUIRED HOSPITAL INTERNSHIPS

In tables 8 and 9 are listed the medical schools and state licensing boards now requiring internships for the M.D. degree and state licensure respectively. Some

* Requires a two-year internship.

medical schools will accept research or other clinical work in lieu of the internship. The effective date of the requirement is shown in both tables. Thirteen schools in the United States and four in Canada exact the internship requisite. The M.D. degree has been conditioned on an internship at the University of Minnesota Medical School since 1915. Rush Medical College, which has required the internship for the M.D. degree since 1919 and the School of Medicine of the Division of the Biological Sciences, University of Chicago, discontinued this requirement in 1936.

As revealed in table 9, seventeen states, Alaska and the District of Columbia require that applicants for licensure possess a hospital internship. The first state exacting the internship was Pennsylvania in 1914 and the last one Vermont, affecting the graduates of 1934 and thereafter.

While some of the medical schools and licensing boards may have their own list of hospitals recommended for intern training, generally the Council's list of hospitals approved for internships is followed.

passed 4,109 candidates, Pennsylvania 2,385, Illinois 1,991, California 1,584, Ohio 1,423, Michigan 1,119 and Massachusetts 1,101. All other states passed less than 1,000. Eleven states passed less than 100 and New Mexico and Wyoming only nine. The percentage of candidates who failed in the examinations in the past five years is given in the last column. The proportion of failures in all states has increased from 7.6 per cent in 1932 to 10.1 per cent in 1936. In the five year period, 46.5 per cent of the applicants failed in Massachusetts. The high percentage in this state is due to the fact that by law the licensing board is required to admit to its examination the graduates of

unapproved schools, many of whom repeatedly fail. A bill was passed in Massachusetts in 1936 giving the board of medical examiners approving authority. The board members are planning to visit the medical schools of Massachusetts and, together with questionnaires similar to those used by the Council in its recent survey of medical schools, plans to establish a list of recognized schools. The effect of the amendment to the medical practice act, however, will not be felt until after 1940, when it goes into effect.

CANDIDATES EXAMINED FROM 1932 TO 1936 INCLUSIVE

In table 10 are listed the number of candidates examined in the various states, territories and possessions in the last five years, 1932-1936 inclusive, showing those who passed and failed. In this period New York

CHART 1.—STATES REGISTERING OTHER THAN GRADUATES OF APPROVED MEDICAL SCHOOLS—1936

The states in black registered more than 5 such candidates, those shaded, 5 or less.

Map copyright by Rand McNally & Company, Chicago

The fourth highest proportion of failures was in New York, with 19 per cent. The comparatively high percentage in this state is occasioned by the fact that New York admits a great many graduates of foreign medical schools to its licensing examination. Arizona had 20 per cent failures, the second highest, Connecticut 19.4 per cent, Nevada 18.8 per cent, Florida 16.2

per cent and Delaware 16 per cent. Florida has no reciprocal relations with any state, all candidates applying being required to take the licensing examination. Graduates of earlier years, it appears, experience difficulty in passing examinations. On the other hand, Kansas, Montana, Nebraska, New Hampshire, New Mexico, Oklahoma, South Carolina, South Dakota and Vermont—nine states—had no failures. Alabama, Arkansas, California, Colorado, the District of Columbia, Georgia, Idaho, Illinois, Indiana, Iowa, Kentucky, Louisiana, Maine, Michigan, Minnesota, Mississippi, Missouri, New Jersey, North Carolina, Ohio, Oregon, Pennsylvania, Tennessee, Texas, Utah, Virginia, Washington, West Virginia and Wisconsin—twenty-nine states—had less than 5 per cent of failures. A total of 30,803 candidates were examined in the five years from 1932 to 1936 inclusive, of whom 28,149 passed and 2,654 failed, 8.6 per cent. These figures represent examinations given and not individuals. A candidate who fails more than once in a given year has not been counted twice, but should he fail in one of the succeeding years in another state he is counted in that state also. Likewise, if a candidate fails and later passes, whether in the same or a later year, he is counted as passed and failed. With a total of 2,654 failures for the five year period, it seems likely that there were approximately 27,500 individuals examined. It is to be assumed that the majority of those who fail are later reexamined and licensed in some state. This figure gives a fair estimate of the number of physicians added to the profession each year. Table 5 gives exact totals

on this point for the years 1935 and 1936. From this table it can be seen that there has been a gradual increase in the number of physicians examined.

REGISTRATION 1904-1936

A study of totals and percentages (table 11) for each year beginning with 1904 is of interest. The number (6,210) who passed in 1936 was 367 more than the number who passed in 1935 and only 534 more than in 1904. The number licensed without examination, 2,745, was 553 more than in 1935. Contrasting these figures with those for 1904 will show the great use being made of this system of licensure. By all methods, 8,955 were registered, 920 more than in 1935. This figure represents the largest number of candidates registered since 1904.

Of those examined 10.1 per cent failed in 1936, while 9.1 per cent failed in 1935. While these figures represent those registered in the years given, they do not in all states represent the number licensed in a given year. Licenses are withheld in many states, as indicated in the text describing table 1.

It will be seen that there has been no constant increase or decrease in the total number of candidates registered from 1904 to 1933, although since 1906 the number licensed without examination has been increasing, owing to the universal system of endorsement and the recognition of the certificate of the National Board of Medical Examiners. The decrease in the number registered in 1918 was due to the sudden withdrawal of physi-

cians and recent graduates from civilian life. Again in 1922 there was a notable reduction, this figure representing the small class that began the study of medicine in 1918. There was, however, a substantial increase in the number registered in 1934 and 1935 and a still larger increase in 1936, both by examination and by endorsement. This is probably accounted for by the fact that medical schools are graduating larger classes, 5,101 in 1935 and 5,183 in 1936. The enrolment in

CHART 3.—STATES REGISTERING GRADUATES OF MEDICAL FACULTIES ABROAD.—1936.

Map copyright by Rand McNally & Company, Chicago

The states in black registered more than 5 such graduates, those shaded, 5 or less.

(CONTINUED FROM PAGE 1423)

medical schools for the college sessions 1935-1936 and 1936-1937 and subsequent years in many cases has been and will be reduced.

GRADUATES OF OTHER THAN APPROVED MEDICAL SCHOOLS AND OSTEOPATHS REGISTERED

In table 12 will be noted the total number of graduates of those institutions which have been classified as unapproved who were registered with or without examination in 1933, 1934, 1935 and 1936.

TABLE 13.—*Graduates of Schools of Osteopathy Registered by Medical Licensing Boards—1933-1936*

Ten states, Alaska and Hawaii in 1936 registered 220 graduates of unapproved medical schools, 201 by examination and nineteen without examination.

The number of unapproved graduates increased by ninety-seven the number registered in 1935. One each was licensed in Florida, North Carolina, Wisconsin, Alaska and Hawaii. The graduate licensed in Florida was required to repeat his senior year's work in an approved medical school. New Mexico permitted one such a graduate to be examined by virtue of the fact that he served in the marine service. No undergraduates were licensed, although five were examined. The thirty-one licensed by examination in Ohio, five in New Jersey by examination and one by endorsement, two in Kentucky by endorsement and thirteen in New York by endorsement are graduates of the Eclectic Medical College of Cincinnati, an unapproved institution. This school has not enrolled any new students for the present college session and plans to discontinue in 1939. The seventy-seven registered in Massachusetts represented mainly two unapproved schools located in that state and a few elsewhere. This state by law is required to admit to its examination a graduate of any chartered medical school but in 1936 amended its medical practice act giving the medical board approving authority. The new law goes into effect in 1940. Eighty-four graduates of the Chicago Medical School, an unapproved institution, were registered in Illinois by examination in 1936.

In the four year period shown, 493 graduates of unapproved schools and undergraduates were registered by examination and forty-one by reciprocity and endorsement, a total of 534.

Chart 1 indicates by shaded lines those registering fewer than six graduates of unapproved medical schools, and by a solid area those registering more than five such candidates during 1936.

In table 13 are given the total number of graduates of osteopathic schools who were registered with or without examination in 1933, 1934, 1935 and 1936.

In 1936, six states registered forty-three by examination and forty-three by endorsement of credentials.

These osteopaths were registered in Colorado, Connecticut, Massachusetts, Texas, Wisconsin and Wyoming. Sixty-four osteopaths failed of registration by examination, one each in Colorado and New Jersey, five in Connecticut, eight in Texas and forty-nine in Massachusetts.

These osteopaths were granted the right to practice medicine or surgery or both, by the board of medical examiners. These facts are shown graphically in chart 2.

In the four year period 1933-1936, 248 graduates of osteopathic schools secured the privilege of practicing medicine, surgery, or both, in seven states and the District of Columbia.

In Colorado, osteopaths are admitted to the examination for a license to practice medicine. They have no separate board. The statute of Colorado is silent with respect to the scope of practice authorized by a license issued to osteopaths.

The Connecticut statute provides that any registered osteopath may practice either medicine, surgery or both, as the case may be, after passing a satisfactory examination before the medical examining board.

The Massachusetts statute, by definition, includes osteopathy in the practice of medicine and does not differentiate the type of license issued to an osteopathic applicant. The medical practice act requires that any applicant for a license to practice must be in possession of a degree of doctor of medicine, or its equivalent, from a legally chartered medical school that gives a full four-year course of instruction of not less than thirty-two weeks in each year. As has been said, the Massachusetts statute has been amended.

Osteopaths who are duly registered and licensed to practice osteopathy in the state of New Jersey, who

TABLE 14.—*Graduates of Approved Schools and Others Registered—1922-1936*

Date	Graduates of Approved Schools		Others		Totals

1936.....	7,904	88.3	1,051	11.7	8,955

present three years of practice of surgery in a hospital approved by the board of medical examiners, may be admitted to the examination to be licensed to practice medicine and surgery.

The statutes of Texas provide for the issuing of a license to practice medicine only. So far as the statutes indicate, the osteopaths are not restricted in their field of practice.

In Wisconsin and Wyoming, osteopaths are granted the right to practice surgery.

It is to be regretted that such persons as those described in tables 12 and 13 are granted the right to

(CONTINUED FROM PAGE 1427)

practice. The medical profession should be ever watchful and untiring in its efforts to prevent osteopaths and others from gaining the legal right to practice medicine or surgery, for which their training is wholly inadequate. If the licensing boards were more fully conscious of their responsibility to protect the citizens of their respective communities from ignorance and incompetence masquerading as medical skill, we should not continue to have year after year licenses granted to persons whose training falls so far short of the currently accepted standards of medical education.

SOURCE OF PHYSICIANS REGISTERED

The educational fitness of the individuals registered in the last fifteen years, 1922-1936, is shown in table 14. Of the 8,955 registered by all methods in 1936, 7,904, or 88.3 per cent, graduated from approved medical schools and there were 1,051, 11.7 per cent, other practitioners registered. In the computation of these figures, all schools rated as class A and B by the Council on Medical Education and Hospitals since 1907 are classified as approved. In the column "Others" are included graduates of institutions prior to 1907, of foreign faculties of medicine, class C graduates, undergraduates, osteopaths, and graduates of schools that have been refused all recognition as medical schools.

ANNUAL REGISTRATION

Eighteen states require that all physicians licensed register annually, whether or not they reside in the state. These states are:

Arkansas (Eclectic Board only)	Minnesota
California	Nebraska
Colorado	Nevada
Connecticut	New York
Florida	North Dakota
Idaho	Oregon
Iowa	Pennsylvania
Kansas	Texas
Louisiana	Utah

Five states—Alabama, Delaware, Georgia, Mississippi and North Carolina—require physicians to pay annually an occupational or commercial tax. In New Mexico, annual registration legislation is pending. The fee for this registration is generally \$2.

GRADUATES OF FACULTIES OF MEDICINE ABROAD

A study of the number of Americans pursuing medical courses in Europe has been carried on by the Council since 1931, when it became evident that great numbers of Americans were going to Europe to study. There are now about 1,500 American students studying abroad who apparently plan to return to the United States to practice. Graduates of faculties of medicine abroad examined for licensure in 1936 are presented in table 16. These represent both American and foreign born physicians. Sixty-seven medical schools and six licensing corporations of fourteen European and two Latin American countries were represented. There were 588 examined, of whom 380 passed and 208, 35.4 per cent, failed. The numbers examined, passed and percentage failed for seven years are shown in table 17. As will be noted, the number being examined is steadily increasing.

In addition to the figures given, 264 graduates of foreign medical faculties were licensed in 1936 without examination and 237 of the 264 so registered were granted licenses in New York on the basis of their

foreign diplomas or licenses, while the remainder (twenty-seven) had already been examined by a state board in this country and were merely migrating.

Graduates of foreign medical faculties were licensed in thirty states; in twenty-seven states, Hawaii and Puerto Rico by examination and in thirteen states without examination.

The increase in the number examined in 1936 represents mostly the Americans who began the study of medicine in 1930. In 1933 the Federation of State Medical Boards adopted a resolution to the effect that no student matriculating in a European medical school subsequent to the academic year of 1932-1933 will be admitted to any state medical licensing examination who does not present satisfactory evidence of premedical education equivalent to the requirements of the Association of American Medical Colleges and the Council on Medical Education and Hospitals, and graduation from a European medical school after four academic years of attendance, and further submits evidence of having satisfactorily passed the examination to obtain a license to practice medicine in the country in which the medical school from which he is graduated is located. This policy of the federation has been made effective by individual action on the part of the state licensing bodies and the National Board of Medical Examiners and will have its desired effect in the future.

In 1934 the Federation of State Medical Boards passed a resolution recommending to its constituent boards that, until adequate information is available, these boards deny graduates of foreign medical schools admission to the licensure examination. However, such candidates, as has just been mentioned, were registered in thirty states.

Several years ago the governments of many European countries sent representatives to this country to discuss appropriate measures for dealing with students from the United States. By the raising of entrance requirements, reduction in enrolment and careful scrutinizing credentials, the number studying abroad should be reduced.

Chart 3 shows in graphic form the states which during 1936 registered graduates of foreign medical faculties by examination, endorsement or both. From a perusal of tables 2 and 3 it can be ascertained how

TABLE 17.—*Graduates of Faculties of Medicine Abroad Examined—1930-1936*

Date	Number Examined	Passed	Percentage Failed
1930.....	167	92	44.9
1931.....	158	91	42.4
1932.....	182	96	47.3
1933.....	200	129	35.5
1934.....	285	170	40.2
1935.....	437	202	53.9
1936.....	588	380	35.4

many were licensed by both these means in the various states. New York, as has been brought out, licensed 454 foreign graduates of the 644 so registered. Of these, 217 were examined and 237 registered without examination. The next highest figure, thirty-seven, were examined in Maryland, while in New Jersey eighteen were examined and eight licensed without examination. The states in black in the chart licensed more than five graduates of foreign schools; those shaded, five or less.

In table 15 are assembled figures showing the standing during the six year period 1931-1936 of the graduates of faculties of medicine outside the United States and Canada admitted to licensing examinations in this country. A similar tabulation is presented for the year 1936. One hundred and twenty-eight schools and eight of the licensing corporations of Great Britain were represented. During the five year period (1931-1935) 1,282 were examined and in 1936, 588. The largest number represented the Regia Università di Napoli, 119, of whom 61.3 per cent failed. The Universität Wien in the five year period was second, eighty-nine, of whom 31.5 per cent failed. There were eighty-four from the Regia Università di Roma with 53.6 per cent of failures, while the University of Edinburgh, with sixty-eight examined, had 8.8 per cent failures. A study of the percentage failed is of interest. Here again an attempt has been made to show procedure over a period of years, and if an individual fails or is examined in various states he is recorded as such for a given year.

BASIC SCIENCE BOARDS

In nine states and the District of Columbia a certificate in the basic sciences is a prerequisite to a license to practice medicine. This certificate is obtainable after

TABLE 1.—States Having Basic Science Laws and Year of Enactment

State	Year Enacted
Arizona	1933
Arkansas	1929
Connecticut	1925
District of Columbia	1929
Iowa	1935
Minnesota	1927
Nebraska	1927
Oregon	1933
Washington	1927
Wisconsin	1925

examination in the majority of instances. Boards for certification of candidates in the basic sciences functioned during 1936 in Arizona, Arkansas, Connecticut, the District of Columbia, Iowa, Minnesota, Nebraska, Oregon, Washington and Wisconsin. The newest addition to this group is Iowa, whose basic science board operated for the first time in 1935. The Supreme Court of Arizona voided the basic science act of that state in 1936 but the legislature reenacted the law without change. No other basic science act was passed in 1936. In 1937, according to data submitted to the Bureau of Legal Medicine and Legislation of the American Medical Association, basic science legislation was introduced in Colorado, Georgia, Kansas, Maine, Michigan, New Mexico, Oklahoma, Tennessee, Utah, West Virginia and Wyoming. In addition, amendments to existing laws were proposed in Nebraska and in Oregon.

Statistics based on the number of candidates certified in 1936, and those who failed to secure this certification, together with the totals for other years shown for comparison, are included in the accompanying tabulations.

In table 1 is shown the years in which the various basic science acts were enacted.

In table 2 will be found the subjects in which examinations were conducted in the respective states and the District of Columbia. The subjects included in basic

science examinations are specified by the basic science acts. The examining boards may neither add to nor subtract from such subjects. Since the table was last published,¹ no legislative changes have occurred with respect to examination subjects.

Applicants examined during 1936 in the various groups—physicians or medical students, osteopaths, chiropractors, and those unclassified—are included in table 3. There were 1,098 examined by the ten boards. Of this number 1,032 were doctors of medicine or medi-

cal students (referred to hereafter for clarity as physicians), thirty-two osteopaths, fifteen chiropractors, and for nineteen it was not possible to determine what profession they represented. In applying for a basic science certificate it is not necessary in several of the states to mention the school of practice, but by checking the biographic records of the American Medical Association it has been possible to determine what profession the majority of the candidates represented. The remainder compose the unclassified group. Of the physicians examined 13.7 per cent failed, of the osteopaths 56.3 per cent, of the chiropractors 73.3 per cent and of those unclassified 57.9 per cent. There were 891 physicians who passed, fourteen osteopaths, four chiropractors and eight unclassified. Minnesota examined the largest number, 271, of whom 19.6 per cent

bia, Iowa and Washington licensed none without examination.

Table 5 shows the number of candidates examined and certified from 1927 to 1936 inclusive. In 1928, when five boards were functioning, there were 646 physicians examined, of whom sixty, or 9.3 per cent, failed and fifty-nine other practitioners, of whom twenty-eight, or 47.5 per cent, failed. In 1936, 1,042 physicians and

thirty-six other practitioners were certified. During the ten year period a total of 6,971 physicians were examined, of whom 11.6 per cent failed, and 661 other practitioners, of whom 52.5 per cent failed. During this period 935 physicians were certified without examination, while only fifty-two other practitioners were so registered.

Altogether, 7,462 certificates have been issued by basic science boards since 1927, of whom 7,096 were granted to physicians and 366 to other practitioners. From the high percentage of failures in the other practitioner group it seems apparent that the enforcement of basic science laws affects most seriously this group. Examination of the records of a considerable number of states having basic science laws will show that before such laws were enacted the number of other practitioners appearing for examination and licensure was very considerable and was growing.

The basic science board seems desirable in states having a multiplicity of examining and licensing boards. The object of these boards has been to provide a means of insuring that all candidates seeking authority to care for sick and injured people shall first possess a reasonable knowledge of the sciences fundamental to the healing art.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners, organized in 1915, conducts examinations and awards successful candidates a certificate, which is regarded as an adequate qualification for the practice of medicine. Since 1922 its examination has been given in three parts, parts I and II being written examinations and part III a practical and clinical oral examination. In the following paragraphs are presented data regarding the examination and the issuance of certificates and include tables enumerating the results of examinations in parts I, II and III for each calendar year, excluding duplication by counting the last examination if more than one part is taken within the year, and also of those certified or failing of certification. Figures from compilations not reproduced here are also discussed. Similar data have been presented in the State Board Number of THE JOURNAL for nineteen years.

Four examinations were held in parts I and II during 1936, at which 1,344 and 768, respectively, were examined. In part I, 858 passed and 123, 12.5 per cent, failed, while in part II, 716 passed and 50, 6.5 per cent, failed. There were 363 who took incomplete examinations in part I. This examination is arranged for candidates taking part I at the end of their second medical year, who are attending schools, the third year curriculum of which includes courses in one or two subjects of part I. The subjects thus postponed may be taken at any examination period after the candidate has completed them in his medical school. Also listed under this heading are those who wish to spend some additional time on one or two subjects. Incomplete examinations were not included when computing percentages, since they represent neither a candidate eligible for certification nor a failure. Two candidates took incomplete examinations in part II.

Since 1922, a total of 14,287 examinations have been given in part I and 7,402 in part II. From 1922 to 1936 inclusive, 9,160 individuals were successful in passing

part I, and 6,631 in part II. The figures for those examined include 3,656 incomplete examinations in part I and thirty-five in part II. The figures cover the totals of each examination given during a calendar year and include some who fail and are reexamined during the same year and also some who pass part I and II in the same year. Therefore they represent examinations conducted rather than individuals examined. In the fifteen year period since 1922 there were 1,471 failures in part I, 13.8 per cent, and 736 in part II, 10.0 per cent.

In 1922, 388 were examined in part I with 20.3 per cent failures as compared with 1,344 in 1936 with 12.5 per cent failures. In part II in 1922, 109 were examined and 17.4 per cent failed, while, in 1936, 768 were examined and 6.5 per cent failed.

The results of examinations in part III for the fifteen year period 1922 to 1936 inclusive are presented in table I, reproduced here. In 1936, 576 were examined, as compared with only twenty-eight in 1922. Of the number examined in 1936, twenty-nine, or 5.0 per cent, failed. The highest percentage of failures was in 1927,

TABLE 1.—Examinations in Part III

Examinations of	Total Examined	Passed	Failed	Percentage Failed
1922.....	28	28	0	0.0
1923.....	76	75	1	1.3

1933.....	552	527	25	4.5
1934.....	581	548	33	5.7
1935.....	598	578	20	3.3
1936.....	576	547	29	5.0
Totals.....	5,375	5,120	255	4.7

when 294 were examined and twenty-two, 7.5 per cent, failed. During 1936, 547 were granted certificates. In fifteen years, 5,375 were examined, of whom 5,120 were granted certificates and 255, 4.7 per cent, failed. Here again a candidate having failed may subsequently receive a certificate.

From 1915 up to and including 1936, 5,387 certificates have been granted.

The number of individuals examined during any one year are given in table 2. The classification as passed or failed, in cases in which more than one examination has been taken in a given year, was based on the results of the last examination during the year in question. For example, if in 1936 a candidate passed part I but later failed part II, he is listed as having failed. Taking this into consideration, there were 2,515 who took the examination of the National Board of Medical Examiners during 1936, as compared with 525 in 1922. A total of 19,358 passed one or more of the examinations in the fifteen years shown and 2,183, or 10.1 per cent, failed. Incomplete examinations have been taken by 3,491 individuals, many of whom have since received certificates.

Diplomates licensed on the basis of their credentials in the United States have increased from two in 1917 to 540 in 1936, 3,561 having been so licensed since the National Board was created. A total of 5,387,

however, have received the certificate of the National Board. In 1936, 540 diplomates were registered on the basis of credentials in forty-one states, the District of Columbia, Alaska, Hawaii and Puerto Rico.

The certificate of the National Board of Medical Examiners is granted recognition by the licensing boards of forty-two states, the District of Columbia, Alaska, Canal Zone, Hawaii and Puerto Rico. Some of these boards, however, have additional requirements.

Alabama	Hawaii	Montana	Pennsylvania
Alaska	Illinois	Nebraska	Puerto Rico
Arizona	Indiana	Nevada	Rhode Island
Arkansas	Iowa	New Hampshire	South Carolina
California	Kansas	New Jersey	South Dakota
Canal Zone	Kentucky	New Mexico	Tennessee
Colorado	Maine	New York	Utah
Connecticut	Maryland	North Carolina	Vermont
Delaware	Massachusetts	North Dakota	Virginia
District of Columbia	Minnesota	Ohio	Washington
Georgia	Mississippi	Oklahoma	West Virginia
	Missouri	Oregon	Wyoming

Diplomates of the National Board of Medical Examiners are admitted to the final examination given by the Conjoint Examining Boards of England and Ireland and the Triple Qualification Board of Scotland. The certificate is also recognized in South Africa, Spain, Syria and Turkey.

Five medical schools now require their students to pass either part I of the National Board examination or parts I and II. Several other schools give their students the option of taking the National Board examination or the school's comprehensive examination. In one or two schools, passing the board's examination in part I excuses the candidate from a portion of the final comprehensive examination given at the end of the fourth year.

Because many graduates of European medical faculties are applying for internships in this country, the Council on Medical Education and Hospitals at a meeting in February 1936 voted that, "when suitable graduates of class A schools of the United States and Canada

STATE BOARD REPORTS

In this issue the Council on Medical Education and Hospitals presents the thirty-fifth annual review of medical licensure. In the licensing examination of the graduates of sixty-seven medical schools in the United States and nine in Canada, 6,906 candidates were examined with 10.1 per cent failures. From the schools in the United States there were 5,705 examinees with 4.3 per cent failures. The New York Medical College and Flower Hospital, Georgetown University School of Medicine and Tufts College Medical School had among their graduates the unenviable record of 22.5 per cent, 21.8 per cent and 21 per cent, respectively, of failures.

The increment of the medical profession consisting of physicians licensed for the first time was 6,166, which is greater by 659 than the number so licensed in 1935. From table 6, showing the distribution of these physicians by sections, it is evident that practically half of the total were licensed in the Middle Atlantic group of states and in the East North Central group.

Although more than thirty-five years has elapsed since the publication of the Flexner report, there are still ten states which license graduates of unrecognized medical schools, Illinois leading with eighty-four and Massachusetts taking second place with seventy-seven. The percentage of licensees who are graduates of unrecognized schools has increased in the last four years from 6.3 to 11.7.

Six hundred and forty-four graduates of schools outside the United States and Canada were licensed. All but 190 of these were licensed in New York. Of those who tried the examinations, 35.4 per cent failed. The candidates represented seventy European faculties and three in Latin America. Among their graduates, in many instances, the record of failure was higher than 50 per cent.

The influence of the National Board of Medical Examiners has steadily increased since its inception in 1915. Five hundred and forty-seven certificates were awarded in 1936. Forty-two states and the District of Columbia have recognized the diploma of the National Board.

THE SIGNIFICANCE OF ALLERGY IN DISEASE

A field as new and as vigorously studied as that encompassed by the term "allergy" receives constant modification and revision.¹ Goldsmith² states that its meaning has now been broadened to include specific changes of sensitiveness to substances other than infective agents. It will not, however, stand being confined within the bonds of too strict a definition. In his view the most practical definition of allergy today is "a specific change in the degree of sensitiveness towards a definite substance or physical stimulus on the part of an individual or of one or more of his tissues." Dowling³ feels, however, that there is little prospect of arriving at a definition of allergy that can be universally accepted. In the one type of allergic reaction in which the mechanism is to a large extent known, namely, sensitivity to foreign proteins, the reaction has been demonstrated to be the result of antibody-antigen interaction. Opie⁴ also points out that the meaning of allergy varies widely with usage. He feels it desirable to apply this term as originally proposed by Pirquet to the changed state with relation to antigens that follows their introduction into the body rather than to the phenomena of sensitization alone. In this sense, Opie states, it includes both the tissue changes at the site of contact with the antigen and the acute functional disturbances such as anaphylactic shock, following dissemination of antigen by way of the blood stream. It is inadvisable, he believes, to apply it to changes not related to the phenomena of immunity.

The meaning of the term is inextricably bound up with the conception of what constitutes allergic etiology. According to Goldsmith, although allergy cannot be given a strict etiologic definition there is one etiologic idea which was an essential feature of Pirquet's conception; namely, that the altered reactivity was caused by the previous contact or contacts with the substance or infective agent. Dowling believes, however, that it is possible that sensitivity may be the result of circumstances other than previous contact; for example, an illness. Even when dealing with atopy, which is a term coined especially to include certain definite types of allergy, the meaning is not entirely uniform. An atopic dermatosis, according to Goldsmith, is an allergic disturbance in which the paramount causal factor is an inherited state called "atopy." Coca also demands for atopy the following attributes: (1) It is peculiar to man; (2) it is characterized by specific circulating antibodies or reagins, which are not precipitins but demonstrable by passive transmission; (3) there is familial and personal history of atopic dermatitis, asthma or hay fever; (4) there is eosinophilia in the blood and

3. Dowling, G. B.: Allergy, Brit. J. Dermat. & Syph. 48:601 (Dec.) 1936.

4. Opie, E. L.: Significance of Allergy in Disease, Medicine 15:477 (Dec.) 1936.

exudates; (5) intracutaneous tests are positive and patch tests negative; (6) there is relief on avoidance of offending circumstances and recurrence on exposure, and (7) atopens are usually protein. Dowling supplements this conception of atopy by citing the evidence indicating that atopic eczema is due to food allergy. Sensitivity to foods is common in atopic eczema, cutaneous tests to extracts of foods are often positive, and both children and adults have been said to improve on a lactovegetarian diet or on diets from which the foods to which they give positive reactions are rigidly excluded.

Allergy, according to Opie, is essential for the production of certain diseases. A heightened inflammatory reaction with accumulation of both granulocytes and mononuclear cells is characteristic of tissue sensitization. Such inflammation follows the usual course with primary exudation of polymorphonuclear granulocytes, followed by accumulation of histiocytes with ability to act as phagocytes. The course and lesions of certain infectious diseases are hence profoundly modified by the phenomena of sensitization. Allergic inflammation, which is the characteristic manifestation of sensitization of tissue, is produced by many micro-organisms, by products derived from them, by foreign proteins and perhaps by some other substances. With allergic inflammation, all the elements that constitute an inflammatory exudate, namely, serum, fibrin, granulocytes, including eosinophilic leukocytes, and histiocytes, accumulate with greater rapidity and in greater numbers than in the normal animal; antibodies if present in the blood are brought to the site of inflammation in increased quantity. Allergic phenomena, Opie believes, are necessary for the production of several common diseases, such as rheumatic fever, glomerular nephritis and lobar pneumonia in addition to tuberculosis and the other practically accepted allergic diseases.

One of the best understood and most fascinating examples of allergic disease is asthma. Since it is commonly true that broadened knowledge of a whole field may be obtained by concentrated effort in one branch, the latter syndrome has received unusual study. As an example of the excellent work now being done in asthma, that by Conybeare and Knott⁵ on the evaluation of the result of bacillary vaccines in asthma may be cited. Autogenous vaccines of gram-negative bacilli of the Friedländer type were found of benefit in the treatment of asthma in cases of moderate severity in which the bronchiolar infection with these organisms was demonstrated. Although specific hypersensitivity did not appear to be concerned in these results, the action of the vaccines in asthmatic patients is probably, to some extent, of a specific character.

The function and purpose of the allergic reactions are receiving close attention, and some attempt is being made to apply the results of laboratory experiments to patients. The increased understanding of tissue

reactions is a step forward. Concerning the allergic subject, however, it is not yet certain that his variation from the normal depends on anything more than a quantitative change.

ACTION OF VIBRION SEPTIQUE TOXIN IN ANIMALS

The anaerobe *Vibrion septique* produces a specific toxin that causes striking effects when inoculated intravenously into laboratory animals. This toxin is unusual in the rapidity of its action, especially on rabbits. A recent study of the gross and microscopic changes produced by the toxin in animals has been reported by Pasternack and Bengtson.¹ The animals used were rabbits, mice, guinea-pigs and pigeons; the results of the studies on these animals disclose certain facts that appear important in understanding the pathologic physiology of fatal human "gas" gangrene due to this organism.

The toxin of *Vibrion septique* has powerful cardio-toxic properties if not even a special affinity for the heart. This organ in almost all animals that survive any length of time shows lesions of some character. Intense capillary engorgement, conglutination and fusion of the red blood cells and occasionally hyaline thrombi are commonly noted. Scattered focal interstitial hemorrhages and some degree of edema are also frequently seen. Hyaline degeneration or Zenker's necrosis is the essential and most important lesion of the heart. It is found in some degree in almost all animals and is probably the cause of death and the explanation for the recorded pathologic changes. In intoxications of short duration the segment of a cell, a whole cell or a few scattered cells or cell groups may show the degeneration. In intoxications of many hours or of several days the musculature may show such advanced necrosis as to be unrecognizable. The picture, in fact, may resemble an intense suppurative process, but micro-organisms are never demonstrable. No previous references to the nephrotoxic properties of the specific toxin of *Vibrion septique* were found by these investigators. Intravenous inoculations, however, produce lesions early and with considerable regularity in rabbits, mice, guinea-pigs and pigeons. The severity of the lesions produced varies more or less with the duration of the intoxication. Gross lesions occur erratically but are not infrequently seen in intoxications of two or three days' duration. The perirenal tissues show hemorrhagic extravasations, and the kidneys red hemorrhagic and yellowish necrotic mottling. Microscopically the lesions in the different animals vary only in degree and in the rapidity with which they develop. The degenerative changes are virtually limited

1. Pasternack, J. G., and Bengtson, Ida A.: The Experimental Pathology and Pathologic Histology Produced by the Toxin of *Vibrion Septique* in Animals. *Bull.* 168, National Institute of Health, U. S. Treasury Dept., 1936.

to the cortex. Some degree of cloudy swelling and hydropic and colloid droplet degeneration of the convoluted tubules and ascending limbs of Henle's loops are usually found. Necrosis of the tubules may occur early in the intoxication but is more usual later. Glomerular congestion and more or less conglutination and later fusion of the red blood cells are seen in most of the animals. The liver shows lesions in only a small percentage of animals. When present they usually occur late and vary from advanced cloudy swelling to irregularly disposed foci of coagulation necrosis of variable size. The spleen is regularly distended with blood, and in a few instances gross hemorrhagic infarcts are present. Congestion, edema and hemorrhage occur inconstantly but not infrequently in the bone marrow. Lesions of the adrenal glands are rare in mice but are seen occasionally in rabbits as gross hemorrhages or hemorrhagic necroses.

Only the brains and cords of rabbits were examined. Ring hemorrhages in the cerebellum, pons and corpus striatum and necrosis of Purkinje cells are occasionally seen. The thymus in rabbits shows congestion, edema, hemorrhages, capillary hyaline thrombi, diffuse infiltrations of polymorphonuclear leukocytes and variable degrees of pyknosis and karyorrhexis of the lymphocytes of the cortex.

The characteristic pathologic changes determined in animals reveal a virulence of this toxin and effects demonstrable in vital organs which indicate the causes for its rapidly fatal action in human beings.

LIBERTY OR LICENSE IN MEDICAL EDUCATION

Freedom of action which contravenes the rights of others is no longer liberty. The state owes to its citizens the duty to protect them from ignorance and incompetence masquerading as medical skill. Health and life itself, our most treasured possessions, must be safeguarded, even at the expense of denying by statutory restrictions the freedom of every individual, trained or untrained, to practice medicine and certain other professions. If this is conceded, it follows that the state in the fulfilment of this obligation must satisfy itself beyond a shadow of doubt of the knowledge, skill and character of those whom it endorses and whose ability it guarantees. Such assurance is derived in part, but only in part, from licensing examinations. It rests in still greater degree on evaluation of the candidate's training and experience. Every state therefore has prescribed a certain minimum of preliminary and professional education as prerequisite to the licensing examination. In order to appraise the credentials of applicants, the state must directly or indirectly evaluate the institutions from which they come and determine which professional schools are in a position to satisfy the requirements of the law.

Recently two prominent educators¹ have expressed rather bitterly their views of so-called interference by standardizing agencies and demanded that universities be granted freedom to follow their own bent. President Capen says:

There has never been a just classification. Either the criteria are too limited, or they are not significant, or they are not applied with sufficient discrimination. The effect of an unfavorable rating is devastating to the institution which is the victim. Invariably its development is retarded. Invariably its morale is lowered. It may be permanently ruined.

The universities have brought on themselves a large part of the ills of which Dr. Capen complains through their own failure to distinguish between standards imposed for the protection of the most vital interests of the public in connection with such professions as law and medicine, and a host of other regulatory measures dealing with vocational training in which the public interest and the universities' responsibility are by no means so clear.

In the thirty-first annual report of the Carnegie Foundation for the Advancement of Teaching, on the other hand, Mr. William S. Learned² points out a fundamental and significant difference between "liberal" and "professional" education:

In professional education, on the contrary, standards of selection and of curriculum achievement both in amount and quality are the inexorable criteria of all procedure. The purpose of such education is to ensure a social service of superlative worth and competence. The agent is comparatively unimportant; regardless of his wishes or career, the community will, in the long run at least, choose those who can do most for it, and it is this impersonal and self-denying attitude which is accepted by all high-minded practitioners as expressing the finest ideals of any profession.

In looking into the intellectual status of prospective teachers, therefore, as of prospective doctors or lawyers, the social critic has the right to disregard the legitimate claims of the individual to a suitable education at his own level and to urge that, in the interests of the cause he serves, certain fixed standards of achievement be enforced. It is not the individual but the service which is at stake. To be sure, at any given time, these standards will be governed by the existing state of knowledge, the economic situation, and the social insight of the community concerned. Nevertheless, whatever they are and whatever they cost, their claim is paramount, in any inventory such as that which is now before us.

The advances in medical education during the last thirty years have been nothing short of phenomenal. History affords no parallel. In large measure these results have accrued through the process of classification applied by the Council on Medical Education and Hospitals and the systematic publication of the results in THE JOURNAL. Far from being "demoralizing" or "devastating," these activities have usually been stimulating and constructive. Those who clamor so loudly for liberty should never forget that in the training of lawyers, dentists and doctors the public has a paramount interest.

Current Comment

SUBACUTE COMBINED DEGENERATION IN PERNICIOUS ANEMIA

Great differences of opinion still exist concerning the reaction of the neurologic manifestations of pernicious anemia to specific therapy. A most thorough study of this problem is the report by Hyland and Farquharson¹ in the December issue of the *Archives of Neurology and Psychiatry*. The wide variation of opinion manifest in previous studies indicates, they believe, that there must be differences either in the treatment administered or in the interpretation of the clinical results. In addition to variation in the mode and quantity of antianemic substances prescribed, there are wide fluctuations in the duration and in the amount of rest, both of which are factors of great importance. The patients studied by these investigators included seventy-four persons with pernicious anemia associated with definite subacute combined degeneration of the spinal cord. On admission to the hospital the patients were kept at complete rest in bed, and potent liver preparations were administered as soon as the investigation was completed. Most patients in the series were given daily by mouth the extract derived from 1,000 Gm. of liver, sometimes receiving in addition from 113 to 142 Gm. of whole liver. The period of complete rest was gradually lengthened. Since 1930 all patients with moderate or severe subacute combined degeneration have been kept at complete rest in bed for an initial period of three months. Since it was found that great improvement occurred most commonly between the third and the sixth month of therapy, the patients were kept in the hospital for long periods, usually from four to twelve months. For purposes of description, the degree of degeneration was classified as mild, moderate or severe, according to the neurologic signs present when the patient was admitted to the hospital. The response to treatment was classified as marked improvement, which consisted of freedom from symptoms and definite improvement in the objective neurologic signs; moderate improvement, which consisted of definite improvement in the neurologic symptoms with little or no change in the principal physical signs, and slight or no improvement. Under the treatment outlined, forty-one patients improved markedly, sixteen showed moderate improvement, in nine the improvement was slight or stationary, and eight died shortly after admission. Analysis of the individual results made it clear that great improvement occurred most frequently in the cases of mild degeneration, but occasionally marked improvement was noted even in the severe cases. In general, the longer the duration of neurologic symptoms the more slowly did improvement become demonstrable, although individual exceptions were noted. The most satisfying symptomatic improvement was in the ability to use the legs. This recovery in gait was dependent on recovery of power, postural sense and muscle tone of the affected limbs. Of almost equal importance was the improvement of the disturbance of

the control of the sphincters that so commonly followed adequate treatment. The most persistent abnormal signs were the altered reflexes, which, however, did show a favorable trend in some cases. It was noteworthy that improvement in motor and sensory function frequently occurred in the absence of any recovery from abnormal reflexes. The authors therefore concluded that, by administration of liver therapy in adequate amounts and for sufficiently long periods, subacute combined degeneration can be prevented, its progression completely arrested and great improvement obtained, especially in cases of short duration.

CARBOHYDRATE METABOLISM AND VITAMIN C

With the development of a chemical method for the estimation of cevitamic acid which is reasonably specific, is adapted to examination of natural tissues and fluids and can be carried out in a short time, records have appeared of many investigations showing the localization of vitamin C in several tissues of the body. The adrenal cortex, pituitary and corpus luteum appear to be especially rich in this substance, although in lesser concentrations it is widely distributed throughout the organism. In view of its labile chemical constitution and widespread occurrence it seems safe to assume that cevitamic acid has an important function in the body, although at present this is but vaguely understood. Through the use of the synthetic vitamin in a wide variety of studies both clinical and experimental, an approach is being made to the elucidation of the part which this indispensable dietary factor plays in physiologic economy. A recent report by Sigal and King¹ indicates that carbohydrate metabolism is influenced by cevitamic acid. Guinea-pigs were used and the index of effect produced was the alteration in the blood sugar concentration (dextrose tolerance) after administration of dextrose by mouth. Each animal was its own control; the normal response was compared to that obtained after ten, fifteen and twenty days on a scurvy-producing ration. Then followed realimentation with vitamin C, and after ten and fifteen days on the adequate diet the dextrose tolerance was again measured. With deprivation of cevitamic acid there was a progressive decrease in the ability of the organism to dispose of the absorbed sugar, evident as early as ten days after removal of the vitamin from the experimental ration. On realimentation, after fifteen days, the blood sugar values during the tolerance test had returned to the normal values. As similar metabolic changes were not observed in other vitamin deficiencies, it is concluded that the effect is more or less specific for cevitamic acid. Older studies² indicated that the loss of body weight during the development of acute scurvy cannot be accounted for entirely by the accompanying partial inanition; the present investigation points to a fundamental difficulty in metabolism of absorbed carbohydrate as an explanation. The evidence emphasizes again the manifold importance of vitamin C in the chemistry of living processes.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

State Medical Meeting at Del Monte, May 2-6.—The sixty-sixth annual session of the California Medical Association will be held at the Hotel Del Monte, Del Monte, May 2-6, under the presidency of Dr. Edward M. Pallette, Los Angeles. Out-of-state speakers include:

Dr. Jesse G. M. Bullowa, clinical professor of medicine, New York University College of Medicine, New York, A Summary of Changes in the White Blood Cells in Various Diseases.

Dr. Norman F. Miller, professor of obstetrics and gynecology and head of the department and Bates professor of diseases of women and children, University of Michigan Medical School, Ann Arbor, The Uterine Cervix: Its Disorders and Their Management.

Dr. Cyrus C. Sturgis, professor of internal medicine and director of the department, University of Michigan Medical School, Ann Arbor, Clinical-Pathologic Conference.

Dr. Louis H. Maxson, Seattle, Spinal Anesthesia—Present Status.

In addition to the independent sectional programs, the following sections will combine in a symposium on pneumonia: medicine; surgery; obstetrics and gynecology; pediatrics; pathology; eye, ear, nose and throat, and radiology. Included among the California speakers on the program will be:

Drs. William J. Kerr, Paul A. Gliebe and James W. Dalton, San Francisco, Some Physical Phenomena Associated with Anxiety States and Their Relationship to Hyperventilation.

Drs. Mark A. Glaser and Clinton H. Thienes, Los Angeles, Experimental and Clinical Studies on Repair of the Dura Mater.

Dr. Emile F. Holman, San Francisco, Recent Advances in the Surgical Treatment of Pulmonary Tuberculosis Through Selective Collapse by Partial Thoracoplasty.

Dr. Frank W. Lynch, San Francisco, Radium Reaction in Cancer of the Cervix.

Dr. Wilber F. Swett, San Francisco, Use of Snake Venom in Post-operative Hemorrhage of the Eye.

Dr. Clarence G. Toland, Los Angeles, The Explosion Hazard in Anesthetic Gas Mixtures.

Mr. William M. Rains, Los Angeles, What the Doctor Should Know About the Law for His Own Protection.

The Past Presidents' Breakfast will be held Tuesday morning and the President's Dinner Tuesday evening. Entertainment will include golf and a skeet shoot. The annual conference on pathology, under the auspices of the cancer commission of the state medical association, will be held May 2 and the radiologic conference, also sponsored by the commission, will take place the same day. The woman's auxiliary will hold its eighth annual session concurrently with the state association.

CONNECTICUT

The Blood Test Marriage Law.—In the first eleven months of 1936 there were 7,347 marriages compared with 11,109 for the similar period in 1935, according to Dr. Stanley H. Osborn, Hartford, state health commissioner. This is the first year in which a blood test was mandatory before the issuance of a marriage certificate. The importance of the law is reflected in the data available showing that many of the persons found with syphilis had no knowledge of the infection prior to the blood test. For the period reported on, syphilis was positively diagnosed in forty-four persons, twenty-four men and twenty women. The law went into effect Jan. 1, 1936.

Meeting on Obstetrics and Gynecology.—The New England Obstetrical and Gynecological Society will hold its spring meeting in Hartford, April 28. The program will include the following speakers, all of Hartford:

Dr. William P. Daly, Transperitoneal Cesarean Section.

Dr. James F. Lynch, Etiology of Breast Tumor from an Endocrinologic Viewpoint.

Dr. Richard C. Buckley, Cerebral Neoplasms as a Complication of Pregnancy.

Dr. Stanley B. Weld, Fibroma of Ovary with Ascites and Pleural Effusion.

Dr. Thomas N. Hepburn, Operation for Prolapse of the Urethra.

Thomas H. Bissonnette, Ph.D., J. Pierpont Morgan professor of biology, Trinity College, Hartford, will be the dinner speaker; his subject will be "Sexual Photoperiodicity in Animals."

Gifts to Yale University.—Gifts amounting to about \$170,000 were announced February 23 by the Yale University Corporation. They included \$67,916 from the Rockefeller Foundation for immediate use in the university for research and publication, \$6,750 from the Josiah Macy Jr. Foundation for medical science research, \$8,459.57 from the Rockefeller

Foundation for research in the medical school, \$4,900 from the Carnegie Corporation of New York City for photomicrography, and \$2,500 from Jeremiah Milbank of New York for poliomyelitis research.

FLORIDA

Society News.—Dr. Benjamin Jablons, New York, addressed a joint meeting of the Brevard, Duval, Orange, Seminole, St. Johns and Volusia county medical societies, April 13, on "Treatment of Nephritis and Its Complications with Tubulin (A New Principle Derived from Mammalian Kidney)."

State Medical Election.—Dr. William H. Spiers, Orlando, was chosen president-elect of the Florida Medical Association at its recent annual meeting in St. Petersburg, and Dr. Edward Jelks, Jacksonville, was inducted into the presidency. Other officers are Drs. Norval M. Marr, St. Petersburg; Reuben N. Burch, Miami, and George L. Cook, Tampa, vice presidents, and Dr. Shaler A. Richardson, Jacksonville, secretary, reelected. The next annual session will be held in Miami.

GEORGIA

Gift to Chinese Medical Students.—Dr. Theodore B. Davis, Newnan, has given his collection of instruments and medical books, accumulated during his fifty-six years of practice, to Dr. Fred P. Manget, for many years a medical missionary in Huchow, China, for the use of students in Dr. Manget's hospital. Newspapers stated that the gift marks the retirement of Dr. Davis from active practice.

Fulton County Meetings.—Dr. James J. Clark, Atlanta, presented a paper before the Fulton County Medical Society, April 1, entitled "The Roentgenological Treatment of the Leukemic States." Dr. Joseph Yampolsky, Atlanta, discussed "Acute Hemorrhagic Nephritis in Negro Children with Special Emphasis on Treatment" before the society, March 18, among other speakers; Dr. John D. Martin Jr., Atlanta, discussed "Congenital Anomalies of the Small Intestine," March 4, and Dr. Christian P. Segard, Leonia, N. J., addressed the pediatric section, March 11, on "Recent Studies in Nutrition with Special Reference to Vitamins and Catalysts."

ILLINOIS

Venereal Disease Clinics.—The first of a series of clinics to be used in venereal disease control was opened in Cairo April 1 by the state health department. Although treatment will be available only to persons unable to pay, a generalized campaign will be centered at the clinic. Financed jointly by the local and state governments, the clinic at Cairo will be under the direct supervision of Dr. Charles L. Weber, city health officer, while a governing board of three citizens and an advisory board of sixteen, representing all civic and professional interests, will determine the policies and direct the program. Blood tests will be made free of charge for any person desiring them. It is expected that eleven clinics will be established throughout the state before July 1. The establishment of these clinics is a part of the state's participation in the national campaign against venereal disease.

Chicago

Personal.—Dr. Gaius E. Harmon, epidemiologist with the Chicago board of health, has resigned to accept a similar position with the Detroit Department of Health.

Society News.—Dr. David O. N. Lindberg, Decatur, discussed "The Mantoux Test: Interpretation in Infection and Disease" before the Chicago Tuberculosis Society, April 15. —At a meeting of the Chicago Pathological Society, April 12, Dr. Dallas B. Phemister spoke, among others, on "Composition of Gallstones Formed in the Common Duct." —Dr. Hans H. F. Reese, Madison, Wis., addressed the Chicago Neurological Society, April 15, among others, on "Insulin Shock Therapy of Schizophrenia." —Roentgenographic examination in obstetrics was discussed before the Chicago Gynecological Society, April 16, by Drs. Robert P. Ball and Howard C. Moloy, New York, and Paul C. Hodges and Adolph Hartung, Chicago. —Dr. Florimond J. LeBlanc addressed the McDonagh Society for Clinical Research, April 16, on "Oxidation and Reduction in Colloidal Chemistry." —The Chicago Ophthalmological Society, among other speakers, was addressed, April 19, by Drs. Theodore E. Walsh on "Some Results of Intranasal Dacryocystotomy in Dacryocystitis" and Raymond Carmody, "Ophthalmoplegia and Exophthalmos as a Complication of Herpes Zoster Ophthalmicus." —Dr. George Halperin addressed the Jewish Physicians Fellowship Club of Chicago, April 12, on "Educational Trends in the U. S. S. R."

INDIANA

Surveys at Central State Hospital.—Two surveys are under way at the Central State Hospital, Indianapolis, one on the causes of dementia praecox and the other on the treatment of neurosyphilis. The former is being conducted by the National Committee on Mental Hygiene under a grant from the Supreme Council of Thirty-Third Degree Scottish Rite Masons, Northern Jurisdiction, while the second is under the auspices of the U. S. Public Health Service, it is reported.

Joint Meeting on Tuberculosis.—The Indianapolis Medical Society and the Indiana Tuberculosis Association held a joint meeting in Indianapolis, April 13. The speakers included Drs. Sayers J. Miller, director of student health service, Purdue University, La Fayette, on "The Tuberculosis Problem in Universities," and Alfred Friedlander, dean and professor of medicine, University of Cincinnati College of Medicine, "Modern Methods in the Diagnosis of Pulmonary Tuberculosis." The following day the Indiana Trudeau Society met with the state tuberculosis association and the speakers included:

Dr. Oscar O. Miller, Louisville, Ky., Unusual X-Ray Lesions in the Chest.

Dr. Orva T. Kidder, Fort Wayne, Early Diagnosis and Collapse Therapy.

Dr. Charles J. McIntyre, Indianapolis, Two Interesting Cases of Tuberculous Pneumonia.

Dr. James H. Stygall, Indianapolis, Basal Lesions.

Society News.—Dr. Willis C. Campbell, Memphis, discussed "Treatment of Fractures of the Neck of the Femur" before the Fort Wayne Medical Society in Fort Wayne, March 2.—At a meeting of the Fayette-Franklin Medical Society in Connerville, March 9, Dr. Francis X. Siegel, Cincinnati, spoke on common diseases and injuries of the eye.—The Floyd County Medical Society was addressed in New Albany, March 12, by Dr. Harry E. Voyles, New Albany, on diagnosis of gallbladder disease.—Dr. Frank C. Walker, Indianapolis, discussed "Causes of Vaginal Discharge and Their Treatment" before the Wayne-Union Counties Medical Society, Richmond, March 21.—Dr. Clyde G. Culbertson, chief of the bacteriologic laboratory of the state board of health, discussed the mechanism of agglutination and isohemagglutinins before the Indianapolis Society of Medical Technologists, February 24.—Dr. John R. Brayton, Indianapolis, discussed common skin diseases and their treatment before the Jay County Medical Society at Portland, March 5.

IOWA

Personal.—Dr. Regnar M. Sorenson, Washington, has been appointed medical director of the recently organized health district number 1, succeeding Dr. William M. Trotter, Maxwell. The district comprises the counties of Lyon, Osceola, Sioux, Plymouth, O'Brien and Cherokee.—Dr. Arthur C. Schach, Burlington, has resigned as director of the Des Moines County health unit.

Lectures on Nutrition.—Dr. William Weston, Columbia, S. C., addressed the Des Moines Academy of Medicine and the Polk County Medical Society in Des Moines, April 7, on "Role of Iodine in Nutrition." He discussed "General Problems in American Nutrition" before the Linn County Medical Society in Cedar Rapids, April 8, and "Adulterated and Deficient Foods" before the Iowa-Illinois District Medical Society, Rock Island, Ill., April 9.

State Department Has Serum Center.—The Iowa State Department of Health recently established a serum center in Des Moines and began the processing of convalescent scarlet fever serum February 20. At regular intervals since September 1936 clinics have been held in Sioux City, Waterloo, Decorah and Des Moines to obtain blood from convalescent scarlet fever patients. For some time the state department of health had been distributing convalescent serum to physicians through the cooperation of the Samuel Deutsch Serum Center at Michael Reese Hospital, Chicago.

KANSAS

New Health Officers.—The following health officers have recently been appointed:

Dr. J. Carroll Montgomery, Wichita, of Sedgwick County.

Dr. Lloyd H. Sarchet, Wellington, Sumner County.

Dr. Frederick E. Dargatz, Kinsley, Edwards County.

Dr. Earl R. Beiderwell, Belleville, Republic County.

Dr. Spencer B. Dykes, Esbon, Jewell County.

Dr. Edgar M. Sutton, Salina, Saline County.

Dr. Willis L. Jacobus, Ottawa, Franklin County.

Dr. Richard F. Boyd, Cimarron, Gray County.

Dr. John G. Swails, Wathena, Doniphan County.

Dr. Ernest C. Moser, Holton, Jackson County.

Dr. Guy B. McIlvain has been appointed city health officer of Clay Center to succeed the late Dr. Robert Algie. Dr. Laurence F. Steffen, St. Marys, has been placed in charge of the newly created full time health unit in Butler County.

KENTUCKY

Personal.—Dr. Earl L. White, U. S. Public Health Service, has been appointed health officer of Crittenden County with headquarters at Marion.—Dr. Joseph M. Ferguson has resigned as medical officer in charge of the Veterans' Administration Facility at Lexington, Ky., because of ill health. Dr. Letcher E. Trent, chief medical officer of the facility at Roanoke, Va., has been transferred to Lexington.

Pediatric Course in Louisville.—A graduate course in diseases of children will be offered at the Children's Free Hospital, Louisville, beginning April 28 and continuing each Wednesday for ten weeks. Members of the staff will discuss interesting cases in the hospital and new methods of treatment will be demonstrated. The course is sponsored by the Kentucky State Medical Association. There will be a charge of \$5. Further information may be obtained from Dr. Philip F. Barbour, Heyburn Building, Louisville.

LOUISIANA

Society News.—At a meeting of the Third District Medical Society in Breaux Bridge, March 4, Drs. Howard R. Mahorner and John G. Pratt, both of New Orleans, discussed management of goiter and the importance of diagnosis in hematuria.—The Tri-Parish Medical Society was addressed in Lake Providence, March 2, by Dr. Guy L. Odom, Jackson, among others, on "General Paralysis of the Insane and the Treatment by Means of Artificial Fever Therapy."

Director of Extension Teaching Appointed.—Dr. Maxwell E. Lapham, Jackson, Miss., has been appointed director of the department of extension graduate teaching at Tulane University, New Orleans, it is reported. He has also been made assistant professor in the graduate school of medicine and the medical school. Dr. Lapham is 36 years of age. In 1925 he graduated from the University of Pennsylvania School of Medicine, Philadelphia, where he served as instructor in obstetrics. In 1932 he was appointed clinical instructor in antepartum and postpartum work to conduct courses for practicing physicians under the auspices of the Medical Society of Virginia, the Medical College of Virginia and the University of Virginia. In 1935 Dr. Lapham joined the staff of the Mississippi State Board of Health to direct a graduate course of obstetrics throughout the state. This program was financed cooperatively by the Commonwealth Fund, the Mississippi State Medical Association, the state board of health and Tulane University School of Medicine.

MAINE

Lectures on Obstetrics.—The division of child hygiene of the state department of health is sponsoring three programs before the Oxford County Medical Association, the first of which was held in Rumford, March 17. The lecturers were Drs. Roland B. Moore and Thomas A. Foster, both of Portland, and the subjects covered antepartum care and normal delivery; motion picture films on the new-born were shown by Dr. Herbert R. Kobes, Augusta, under whose supervision the programs are being offered. The second in the series was to be held in April and the third in May.

MARYLAND

Society News.—Frank W. Notestein, Ph.D., lecturer, School of Public and International Affairs, Princeton University, Princeton, N. J., gave one of the De Lamar lectures in hygiene at Johns Hopkins University School of Hygiene and Public Health, April 6. His subject was "Differences in the Fertility of Important Classes of the Population."

Increase in Communicable Diseases.—There were 47,264 cases of "notifiable" diseases reported to the Maryland State Department of Health in 1936 as compared with 39,487 in 1935. The city of Baltimore reported a total of 29,173, and the counties of the state 18,091. Increases were noted for measles with a total of 7,600 cases as compared with about 2,350 in 1935; 4,348 cases of whooping cough as compared with 1,621 in 1935, and venereal diseases, 12,464 as against 11,985 in the previous year. Meningitis increased from 297 cases in 1935 to 476 in 1936, while typhoid dropped from 483 in 1935 to 269 in 1936. Decreases were also noted for tuberculosis from 3,063 in 1935 to 2,759 in 1936, scarlet fever from 3,693 in 1935 to 2,728 in 1936 and poliomyelitis from 107 in 1935 to thirty-seven in 1936. More than nine tenths of the sickness from communicable diseases reported in the state in 1936 was divided among the venereal diseases, including 9,433 cases of syphilis, which accounted for 25 per cent of the total; children's diseases with 25,338 cases, or more than 50 per cent of the total; the pneumonias with 3,300 cases, tuberculosis with 2,759 and influenza with 822 cases accounted for 15 per cent of the total illness.

MASSACHUSETTS

Hospital News.—The Massachusetts Hospital Association was made permanent February 25, when a constitution and by-laws were approved. The association was organized on a temporary basis a year ago. The officers chosen then were unanimously reelected at the recent meeting: Dr. Henry M. Pollock, Boston, president; Bertha W. Allen, R.N., vice president; Rev. Warren F. Cook, secretary-treasurer, and Dr. Norman C. Baker, Boston, secretary.

Society News.—Dr. Frank A. Pemberton, Boston, addressed the Pentucket Association of Physicians in Haverhill, April 8, on "Progress in Gynecology." Dr. Howard M. Clute, Boston, discussed "Problems of the Upper Part of the Abdomen" before the society March 11.—At a meeting of the Neisserian Medical Society of Massachusetts in Boston, March 31, Dr. Nels A. Nelson, Boston, discussed the "Treatment of Gonorrhea in the Male."—A tag day was held in Boston, March 27, as part of the state campaign for cancer control which is being conducted under the auspices of the Women's Field Army of the American Society for the Control of Cancer.

Memorial to Dr. Clapp.—A memorial tablet in honor of the late Dr. Frank H. Clapp was unveiled March 20 at the Nelson Memorial Library, North Grafton, by Barbara Sanford, his granddaughter. The speakers included Dr. Harlan L. Paine, superintendent of the Grafton State Hospital; Mr. Isidore O. Senecal, president of the Maroon Club, who sponsored the idea of the memorial tablet; Dr. Roy J. Ward, president of the Worcester District Medical Society, and Dr. Enos H. Bigelow, Framingham, formerly president of the Massachusetts Medical Society. Dr. Clapp was for many years a member of the school committee and board of health of North Grafton. He died Feb. 26, 1936, aged 74.

MINNESOTA

State Medical Meeting at St. Paul, May 2-5.—The eighty-fourth annual meeting of the Minnesota State Medical Association will be held at the St. Paul Auditorium, St. Paul, May 2-5, under the presidency of Dr. Alfred W. Adson, Rochester. Sunday the house of delegates will be addressed by Drs. Edward H. Skinner, Kansas City, on "How the Kansas City Profession is Meeting Social Security Problems," and Olin West, Secretary and General Manager, American Medical Association, Chicago, "Better Health Activities." The Russell D. Carman Memorial Lecture will be delivered Monday morning by Dr. Skinner on "Reflections upon the Roentgenology of Fractures." The Citizens Aid Society Memorial Address will also be presented Monday morning. The speaker will be Dr. Robert S. Stone, associate professor of roentgenology, University of California Medical School, San Francisco, on "Irradiation Therapy of Tumors with a Consideration of the Possibility of Supervoltage X-Rays." Monday there will be a Congress of Allied Professions, in which nurses, dentists, pharmacists, hospital executives and social workers will consider factors involved in distribution of medical care. At the evening session the following speakers will discuss "Suggested Solutions of America's Health Problems":

Rev. Alphonse M. Schwitalla, S.J., dean, St. Louis University School of Medicine.

Dr. Martha M. Eliot, assistant chief of the Children's Bureau, U. S. Department of Labor, Washington, D. C.

C. Rufus Rorem, Chicago, Ph.D., director, committee on hospital service, American Hospital Association.

Dr. Maxwell J. Lick, Erie, Pa., president of the Medical Society of the State of Pennsylvania.

At a public health meeting Tuesday evening the speakers will be Father Schwitalla on "The Child and the Physician"; Dr. Nathan B. Van Etten, New York, Speaker of the House of Delegates, American Medical Association, "The Medical Citizen"; Dr. Raymond A. Vonderlehr, Washington, D. C., U. S. Public Health Service, "What the Public Can Do in the Present Campaign for Control of Syphilis," and Dr. Walter C. Alvarez, Rochester, "Quacks I Have Met." The following lectures will also be delivered by guest speakers during the meeting:

Dr. John M. Wheeler, New York, professor of ophthalmology, Columbia University College of Physicians and Surgeons, New York, "Important Injuries About the Eye."

Dr. Francis D. Murphy, clinical professor and director of the department of medicine, Marquette University School of Medicine, Milwaukee, "Hypertensive Heart Disease—Its Clinical-Pathologic Manifestations."

Dr. Lick, "The Doctor Looks at Social Security."

Dr. Van Etten, "Medical Care for All Americans."

Theodore Christianson, Minneapolis, former governor of Minnesota.

In addition to these special features, which include also a Northwest Industrial Medical Conference, Wednesday, papers will be presented by many Minnesota physicians. The woman's auxiliary will hold its annual meeting during the week.

NEW MEXICO

Head of Child Health Division Appointed.—Dr. Hester B. Curtis has been appointed to take charge of the division of child health in the Bureau of Public Health. Dr. Curtis graduated from Yale University School of Medicine in 1932 and was a student at the Harvard School of Public Health, 1935-1936. At the time of her appointment she was associated with the New York State Department of Health, Albany.

NEW YORK

Society News.—The Westchester Society of Gastro-Enterology was organized recently with Drs. Frederic M. Johnson, Yonkers, as president, and Vera L. Collins, Yonkers, secretary. This is the tenth affiliated chapter of the National Society for the Advancement of Gastro-Enterology.—The Academy of Stomatology of Eastern New York was recently organized and held its first scientific meeting in Albany, March 4. The speakers were Dr. Joseph Jordan Eller, New York, on "Dermatologic Lesions of the Mouth and Lip"; Harry Gullifer, D.D.S., Boston, "The Adamantinomas of the Jaw," and Dr. Hayes E. Martin, New York, "Diagnosis and Treatment of Intra-Oral Cancer."—Drs. Isabel Knowlton and Harriet McIntosh, New York, addressed a meeting of the council of the Woman's Medical Society of New York State recently in New York City. Guests of honor were Drs. Maude E. S. Abbott, formerly assistant professor of medicine and curator of the Museum of the History of Medicine at McGill University, Montreal, and Mabel M. Akin, Portland, Ore.

New York City

Personal.—Dr. Adolph G. G. De Sanctis was honored by a dinner, March 14, at the Hotel Ambassador, given by the Association of Italian Physicians in America, marking his accession to the presidency of the Medical Society of the County of New York.

Biggs Memorial Lecture.—The twelfth Hermann Michael Biggs Memorial Lecture of the New York Academy of Medicine was delivered April 1 by Henry C. Sherman, Ph.D., Mitchell professor of chemistry, Columbia University. His subject was "The Bearing of the Results of Recent Studies in Nutrition on Health and Length of Life."

Society News.—Drs. Harry Wessler, New York, and Carleton B. Peirce, Ann Arbor, Mich., addressed the New York Roentgen Society, March 15, on "Pathogenesis of Tuberculosis" and "The Oblique Projection of the Thorax; An Anatomic and Roentgenologic Study," respectively.—Drs. Russell S. Boles and Clifford B. Lull, Philadelphia, addressed the Medical Society of the County of Kings, March 16, on "Hepatic Cirrhosis" and "The Hemorrhages of Pregnancy," respectively.—The Brooklyn Thoracic Society heard a discussion, March 19, of "An Antigen for the Determination of Activity in Tuberculosis," by Drs. Benjamin Gruskin, Philadelphia, Richard H. Bennett, Emanuel Schwartz and Alexander L. Louria.—A symposium on hernia was presented at a meeting of the New York Surgical Society, March 24; the speakers were Drs. Roderrick V. Grace, Vansel S. Johnson, Bradley L. Coley, Carl G. Burdick, David H. M. Gillespie, Norman L. Higinbotham and Allen O. Whipple.

NORTH CAROLINA

State Medical Meeting at Winston-Salem.—The eighty-fourth annual session of the Medical Society of the State of North Carolina will be held at Winston-Salem, May 3-5, under the presidency of Dr. Charles F. Strosnider, Goldsboro. The guest speakers who will address general and sectional meetings include:

Dr. Arthur M. Shipley, Baltimore, "The Biliary Duct Apparatus as a Surgical Problem."

Dr. Algernon B. Reese, New York, "The Operative Treatment of Primary Glaucoma."

Dr. Edward A. Schumann, Philadelphia, "Leaves from a Gynecologist's Notebook."

Dr. David M. Davis, Philadelphia, "Syphilis and Gonorrhea as Public Health Problems."

Dr. John A. Ferrell, New York, "Experimental Approaches Under Way Toward More Efficient Public Health Administration."

Dr. Thomas A. Shallow, Philadelphia, "The Surgical Approach to Foreign Bodies in the Gastro-Intestinal Tract."

The woman's auxiliary will hold its annual meeting during the week and the North Carolina Public Health Association will meet Monday May 3. Tuesday evening there will be a testimonial dinner to Dr. Louis B. McBrayer, Southern Pines, secretary of the society for many years, followed by the president's reception. Headquarters will be at the Robert E. Lee Hotel.

OHIO

Personal.—Dr. Millard C. Hanson, health officer of Mansfield, has been appointed health officer of Toledo, effective April 15.—Dr. Edward O. Morrow, Canton, was recently honored by a testimonial dinner given by the Stark County Medical Society, celebrating his fiftieth anniversary in the practice of medicine.—Dr. Herbert E. Koepke, Cadiz, has been appointed health commissioner of Harrison County, and Dr. William Edward Blair, Lebanon, of Warren County.—Dr. Stewart G. Patton, North Jackson, has been appointed health officer of Mahoning County to succeed Dr. George Y. Davis, Youngstown.

PENNSYLVANIA

Society News.—Dr. Martin E. Rehfuess, Philadelphia, addressed the Cambria County Medical Society, Johnstown, April 8, on "Diagnostic Problems in Gastro-Enterology."—Dr. Charles L. Brown, Philadelphia, addressed the Lackawanna County Medical Society, Scranton, March 30, on hypertension. Dr. Dean D. Lewis, Baltimore, spoke March 15 on tumors of bone.—Dr. Grover C. Weil, Pittsburgh, addressed the Medical Society of Franklin County, Waynesboro, March 19, on compound fractures.—Dr. Franklin Howard Westcott, New York, addressed the Lebanon County Medical Society, Lebanon, April 13, on "Allergy in General Practice with Treatment of Pollinosis and Pollen Asthma."—Dr. Vincent T. Curtin, Scranton, addressed the Northampton County Medical Society, Easton, April 16, on "Fads and Fancies of Infant Feeding."—Dr. Frank A. Evans, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, April 1, on "Treatment of Psychoneurosis in General Practice."

Philadelphia

Personal.—Dr. Louis Lehrfeld has resigned as epidemiologist of the Philadelphia Department of Public Health after twenty-two years' service. Dr. Lehrfeld has been appointed attending surgeon to the Wills Eye Hospital to fill the vacancy caused by the resignation of Dr. Francis Heed Adler, recently appointed professor of ophthalmology at the University of Pennsylvania School of Medicine.—Drs. Isidor P. Strittmatter, Arthur C. Morgan and Thomas R. Currie were guests of honor at the annual dinner of the Northern Medical Association, the oldest medical society in Philadelphia, March 15. The association is 91 years old. Dr. Strittmatter was unable to attend the dinner because of illness.—Dr. Frank C. Hammond, dean emeritus of Temple University School of Medicine, was the guest of honor at a dinner given by the Hammond Pre-Medical Society, March 8, in honor of his sixty-second birthday. Dr. Charles L. Brown, professor of medicine, was the principal speaker.—Dr. Garfield G. Duncan has been appointed chief of service at the Pennsylvania Hospital, filling the vacancy made by the death of Dr. Thomas McCrae in June 1935.—Dr. Joseph C. Doane has been elected an associate editor of the *Pennsylvania Medical Journal*.

SOUTH CAROLINA

Yellow Fever Volunteer Dies.—Charles G. Sonntag of Jackson, one of the volunteers who submitted to inoculation with yellow fever through mosquito bites in the experiment conducted by Major Walter Reed in Cuba in 1900-1902, recently died at the age of 64. Sonntag took yellow fever but survived and has been a farmer for many years. In 1931 he received a gold medal authorized by Congress in recognition of his service in the yellow fever experiment.

TENNESSEE

Personal.—Dr. Milton W. Williamson, Redboiling Springs, recently associated with the Kentucky State Board of Health and formerly with the U. S. Public Health Service, has been appointed associate city health director of Chattanooga.—Dr. Joseph C. Tatum, Waverly, has resigned as health officer of Humphreys County to become health officer of Giles County, succeeding Dr. John U. Speer.—Dr. Robert Knox Galloway, recently health officer of Williamson County and city health officer of Franklin, has been appointed director of health and hygiene in the public schools of Nashville, it is reported.—Dr. Waller S. Leathers, dean and professor of preventive medicine and public health, Vanderbilt University School of Medicine, Nashville, has been reappointed a member of the National Advisory Health Council of the U. S. Public Health Service.—Dr. Edward L. Turner, recently professor of internal medicine in the American University, Beirut, Syria, has been appointed professor and head of the department of medicine at Meharry Medical College, Nashville.

VIRGINIA

Social Work Conference.—The division of public health and medical care of the Virginia Conference of Social Work, of which Dr. Basil B. Jones, Richmond, is chairman, arranged a program on syphilis at the annual meeting of the conference in Richmond April 8-10. Among the speakers were Drs. Dudley C. Smith, Charlottesville; Kinloch Nelson, Richmond; Thomas L. Gemmill, Petersburg; Lonsdale J. Roper, state department of health, Richmond; Ennion S. Williams, Richmond, and Mrs. Norman Ingraham, social worker, University of Pennsylvania Hospital, Philadelphia. The Virginia Mental Hygiene Society also sponsored a program on which the speakers included Drs. Howard R. Masters, Richmond, and David C. Wilson, Charlottesville.

WEST VIRGINIA

Society News.—Dr. Leo Huth, Follansbee, addressed the Brooke County Medical Society, Wellsburg, March 10, on a new method of administering scopolamine in Parkinson's disease.—Dr. John C. Matthews, Huntington, addressed the Kanawha Medical Society, Charleston, March 9, on "Treatment of Gonorrhea in the Male" and Dr. Hugh B. Robins, Charleston, on "Syphilis and Its Social Problem."—At a meeting of the Logan County Medical Society, Logan, March 10, Dr. Walter W. Point, Charleston, spoke on complications of pregnancy and Dr. Andrew E. Amick, Charleston, on child health and social security.—Dr. Will A. Quimby, Wheeling, addressed the Marshall County Medical Society, March 9, in Moundsville, on prevention and treatment of cancer.

GENERAL

Resolution Defines Adequate Diagnosis of Eye Disease.—A resolution adopted at a meeting of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association in New Orleans, February 23, reads in part as follows:

That it is the sense of the Joint Committee on Health Problems in Education and the American Medical Association . . . that the safety of the eyes of school children, the adequate diagnosis of disease and the correct fitting of glasses require examination of children's eyes (beyond rough visual tests performed by teachers or nurses) by a licensed doctor of medicine and, upon his recommendation, by a medical specialist in diseases of the eye, properly known as an oculist or ophthalmologist.

Board to Recommend Health Officers.—A special board has been appointed to advise the United States Conference of Mayors in the appointment of public health officers. Dr. Joseph W. Mountin of the U. S. Public Health Service is chairman of the board; other members are Drs. Allen W. Freeman, dean of the Johns Hopkins University School of Hygiene and Public Health, Baltimore; Wilson G. Smillie, professor of public health administration in the Harvard School of Public Health and recently appointed professor of public health and preventive medicine at Cornell University Medical College, New York; Huntington Williams, health commissioner of Baltimore, and John L. Rice, health commissioner of New York.

National Academy of Sciences.—The National Academy of Sciences will hold its annual spring meeting in Washington, April 26-27. Among the papers of medical interest to be presented are:

- Dr. Simon Flexner, New York, Immunity and Reinfection in Experimental Poliomyelitis.
- Dr. Howard W. Haggard and Leon A. Greenberg, Ph.D., New Haven, Conn., The Effects of Alcohol as Influenced by Blood Sugar.
- Dr. George H. Whipple, Rochester, N. Y., The Romance of Hemoglobin.
- Dr. Francis G. Benedict and Robert C. Lee, Boston, Body Fat as a Factor in Heat Production.
- Edmund Newton Harvey, Ph.D., Alfred L. Loomis, LL.B., and Garret A. Hobart III, Princeton, N. J., and Loomis Laboratory, Tuxedo Park, N. Y., Cerebral Processes During Sleep as Studied by Human Brain Potentials.
- Robley D. Evans, Cambridge, Mass., Elimination of Radium Impurities from the Blood Stream.

Association on Mental Deficiency.—The sixty-first annual convention of the American Association on Mental Deficiency will be held at Atlantic City, May 5-8, with headquarters at Haddon Hall. Among the speakers on the program will be:

- Dr. I. Newton Kugelmass, New York, Management of Epilepsy in Children.
- Dr. Frank V. Willhite, Redfield, S. D., A Program for the Social Control of the Mentally Deficient.
- Dr. George E. McPherson, Belchertown, Mass., Heredity in Mental Deficiency.
- Dr. Adrien S. Bleyer, St. Louis, Maternal Age and Mongolism, a Study of 3,000 Cases.
- Dr. George A. Jervis, Thiells, N. Y., Inherited Biochemical Deficiencies in Certain Types of Feeble-minded.
- George Keezer, Ph.D., Vineland, N. J., Electrical Phenomena of the Brain Among the Feeble-minded.
- Dr. Clarence A. Mills, Cincinnati, Climatic and Weather Factors in the Production and Manifestations of Mental Deficiency.

Meetings in Atlantic City.—The annual informal dinner and general meeting of the American Board of Obstetrics and Gynecology will be held at the Hotel Claridge, Atlantic City, Wednesday evening, June 9. Dr. Charles Gordon Heyd, New York, President of the American Medical Association, will be the principal speaker. Diplomates of the board and others interested in the specialty are invited. Tickets may be obtained at the door at \$2 each.—The Alpha Kappa Kappa Medical Fraternity will hold an alumni luncheon at the Hotel Ambassador, Atlantic City, N. J., June 9, at 12:15 p. m. The entire international council of the fraternity will attend.—Phi Delta Epsilon will hold its annual luncheon during the session of the American Medical Association at the Ritz Carlton, Atlantic City, Thursday, June 10.

Meeting on Allergy.—The Society for the Study of Asthma and Allied Conditions will hold its thirteenth annual meeting at the Hotel Chalfonte-Haddon Hall, Atlantic City, May 1. Dr. Milton B. Cohen, Cleveland, president, will speak on "Observations upon the Transmission of Passive Anaphylactic Sensitivity in the Guinea-Pig." Other speakers will include:

Drs. Warren T. Vaughan and Clement J. Sullivan, Richmond, Va., Blood Surface Tension, Sedimentation Rate and Blood Pressure Responses Following the Ingestion of Allergenic Foods.

Drs. James A. Clark Jr. and Howard C. Leopold, Philadelphia, Prophylactic Treatment for Ragweed Hay Fever—A Statistical Study.

Dr. Joseph Harkavy, New York, Biopsy Studies of Skin Reactions to Tobacco in Vascular Disease.

Drs. Robert Chobot, New York, and George H. Hurwitz, Hartford, Conn., Limitations of Passive Transfer in Food Sensitive Children.

Dr. Abner N. Fuchs, New York, The Interruption of the Asthma Crisis by Tribromethanol (Avertin).

Dr. Alphonse R. Dochez, professor of medicine, Columbia University College of Physicians and Surgeons, New York, will address the annual dinner Saturday evening on "Studies of Upper Respiratory Tract Infection."

International Congress of Radiology.—Special courses in certain fields of radiology are to be offered during the fifth International Congress of Radiology, to be held in Chicago, September 13-17. Lectures will be given each morning of the congress for one hour. The lecturers and their subjects are:

Dr. Henri Coutard, Paris, Roentgen Therapy in Cancer.

Dr. George W. Holmes, Boston, Problems in Roentgenologic Diagnosis.

Dr. Hermann Holthusen, Hamburg, Germany, Fundamentals of Roentgen and Radium Therapy.

Dr. Byrl R. Kirklín, Rochester, Minn., Roentgen Diagnosis in Gastro-Enterology.

Dr. Edwin A. Merritt, Washington, D. C., Special Problems of Radiation Therapy Relating Especially to Treatment of Cancer of the Cervix and Breast.

Dr. Merrill C. Sosman, Boston, Diagnosis of Brain Lesions.

James L. Weatherwax, A.M., Philadelphia, Elementary Physics of Radiation.

Each of the courses will be given in English and will be open to between fifty and a hundred members, who will register for the specific course desired. Those who have already applied for membership in the congress may register by writing to the General Secretary, 2561 North Clark Street, Chicago; those who apply hereafter may register when they submit their applications for membership. It is desired that registration be made as soon as possible. There will be no extra charge for these courses. Complete papers to be presented at the meeting must be in the hands of the secretary by May 1 to allow time for translation and publication.

Government Services

Surgeon General Rossiter Reappointed

Rear Admiral Perceval S. Rossiter has been reappointed surgeon general of the U. S. Navy, following his completion of four years in the office. Dr. Rossiter will reach the statutory age for retirement Nov. 30, 1938. He graduated from the University of Maryland School of Medicine, Baltimore, in 1895 and has been associated with the service since 1903. Dr. Rossiter is now president of the Association of Military Surgeons of the United States and Canada.

Health of the Navy

Striking improvement in the health of the navy was recorded in the annual report of the Bureau of Medicine and Surgery, which covers important activities of the fiscal year 1935-1936 and detailed statistics of diseases and injuries for the calendar year 1935.

There were 51,746 admissions for all causes during 1935, a decrease of 13 per cent from 1934, attributed principally to a decrease in venereal diseases and a low incidence of communi-

cable diseases. Only two of the twenty-seven classes in the nomenclature of diseases and injuries showed percentage increases: all the rest showed decreases ranging from 0.45 for diseases of the mind to 75 per cent for communicable diseases transmissible by intestinal discharges.

Acute catarrhal fever, the navy's designation for the common cold, caused 21.25 per cent of the total admissions, first among single causes of admission. The rate was 8,299 per hundred thousand, compared with 9,974 in 1934. There were 200 admissions for influenza, compared with 432 in the previous year.

Venereal diseases occupied second place among all causes of morbidity and for the third consecutive year showed a decrease from the rate recorded the preceding year. These diseases were responsible for 16.48 per cent of all admissions. The rate was 74.7 per thousand, which was 17.26 per cent less than the rate for 1934 and 44.10 per cent less than the median rate for the five-year period 1930-1934. Gonococcal infection of the urethra caused 13.03 per cent of all admissions and syphilis 3.6 per cent.

There were 220 cases of diseases transmissible by insects and other arthropods, including 147 of malaria, sixty-three of dengue, six of typhus and four of filariasis. Among diseases transmissible by intestinal discharges were thirty cases of amebic dysentery, nine of paratyphoid, six of bacillary dysentery and five of typhoid.

Acute appendicitis caused 1,058 admissions to sick list, second in frequency among diseases of the digestive system, first in number of sick days per case. Acute gastro-enteritis was first in frequency, with 1,081 cases, but only 4.8 sick days per case. Diseases of the ear, nose and throat accounted for 6.9 per cent of the admissions; diseases of the eye, 1.3 per cent; diseases of the genito-urinary system (nonvenereal), 1.8 per cent; diseases of the motor system, 1.6 per cent.

There were 215 original admissions for diseases of the nervous system and 256 for diseases of the mind. In the latter group 251 persons were invalidated from the service. The largest number of the original admissions was for dementia praecox, fifty-seven.

Among 421 original admissions for diseases of the circulatory system, the largest number was 127 for arterial hypertension. There were 464 admissions for benign and malignant tumors, 292 of which were for cysts. Twelve were for carcinoma. There were 439 admissions for hernia.

The rate of admission to sick list for wounds and injuries in 1935 was 61.84 per thousand, somewhat lower than the rate for the preceding year. This cause was responsible for 13.58 per cent of all admissions. Motor vehicle accidents caused 848, or 12.1 per cent, of all accidental injuries and poisonings; 730 of them were received while the men were on leave or liberty. Athletics and recreative sports caused 1,431 admissions. There were no large disasters, but five accidents causing loss of life or injury were reported.

There were 320 deaths from all causes among the navy personnel of 114,188, giving a rate of 2.8 per thousand as compared with 2.73 for the preceding year and the median rate of 3.35 for the preceding five years. Wounds and injuries caused 163 deaths, diseases 149 and poisonings eight. Forty-three deaths were due to motor vehicle accidents and thirty-three to drowning. There were thirty-six suicides and nine homicides. Diseases of the circulatory system caused thirty-six deaths, pneumonia twenty-two, tuberculosis fourteen, cerebrospinal fever eight and appendicitis five. There were 1,397 persons invalidated from the service in 1935.

During the year the naval hospitals at Great Lakes, Ill., and Newport, R. I., were reopened and a general order was issued for creation of the Naval Medical Center at Washington, D. C. to consist of the Naval Hospital, the Naval Medical School and the Naval Dental School. During the year twenty-one naval medical officers completed a six months graduate course in naval medicine at the naval medical school and twenty-six took graduate courses in various universities. The report points out that there is an acute shortage of qualified flight surgeons for the navy. At the end of the fiscal year there were 806 members of the medical corps; twenty-five retired, seven resigned and two died. Fifteen officers were commissioned following an examination in May 1936.

CORRECTION

Primary Friedländer Pneumonia.—In the article by Dr. Saul Solomon in THE JOURNAL, March 20, the sentence beginning at the foot of page 937 and continuing on page 938 should read: "It is aerobic and facultative anaerobic and grows very readily on the ordinary laboratory mediums. In broth there is rapid and abundant growth with turbidity, slimy sediment and pellicle formation."

Report of the Medical Research Council

The report of the Medical Research Council for 1935-1936, which has just been published, describes advances of great interest.

THE MECHANISM OF NERVE TRANSMISSION

The Nobel prize in medicine was awarded in 1936 jointly to Sir Henry Dale, director of the National Institute for Medical Research, and Prof. Otto Loewi of the University of Graz, for their work on the chemical mechanism of nerve transmission. Sir Henry Dale in 1914 became interested in the substance known as acetylcholine, which he found in some samples of ergot. Its potency in stimulating parasympathetic nerve endings and its rapid destruction by hydrolysis suggested the possibility of its physiologic importance. Between 1921 and 1926 a fundamental observation was made on the subject by Professor Loewi. He showed that stimulation of the vagus nerve to a frog's heart liberated a chemical substance, probably acetylcholine, which was itself capable of slowing the heart—the well known effect of vagus stimulation. It seemed as though the vagus acted on the heart by first liberating acetylcholine at the nerve endings. In 1929 an important advance was made when the late Dr. H. W. Dudley, collaborating with Dale, isolated acetylcholine as a normal constituent of an animal organ.

In recent years Dale and his colleagues have studied this problem with much ingenuity. They have shown not only that acetylcholine is the chemical transmitter of the vagus impulse to the heart but also that the same mechanism is responsible for all parasympathetic activities and also for some sympathetic, such as sweat secretion. Acetylcholine was also found to be the effective chemical substance responsible for all nerve transmission, parasympathetic or sympathetic, through ganglions of the autonomic system. In the past year Dale and his colleagues have shown an even wider action—that acetylcholine is the medium through which motor nerve impulses activate voluntary muscle. The results of this brilliant work are at present impossible to foresee. Already it has provided a scientific basis for the discovery by Walker of the action of prostigmin in alleviating myasthenia gravis, and there are indications that some compounds closely allied to acetylcholine, but of greater chemical stability, may have therapeutic importance.

THE VIRUS OF INFLUENZA

The investigations at the National Institute for Medical Research on influenza by Laidlaw, Andrewes, Wilson Smith and Stuart-Harris during the past year have made progress. This work originated in the discovery that an infection diagnosed as influenza in man could be transmitted to ferrets, in which it produced a characteristic feverish and catarrhal condition. This was transmissible to other ferrets, and recovered ferrets were immune for the time against further infection. Later it was found that mice could be infected from ferrets. The infective material from the human nasal mucosa, passed through a fine filter, was still infective when instilled into the ferret's nostril, indicating an ultramicroscopic virus. Here was the foundation of a new experimental method of investigating influenza, which already has yielded important results.

It has been shown that the virus originally isolated at the National Institute for Medical Research has a world-wide diffusion. Francis of the Rockefeller Institute, New York, has isolated strains of the virus from epidemics in Puerto Rico,

Philadelphia and Alaska, which were indistinguishable from those obtained by the British workers. This result has been confirmed by Dutch and Russian workers. A further step is the transmission of ferret influenza to man, which dispels the doubts of certain responsible investigators, especially in Germany, as to the connection between human influenza and the disease transmitted to ferrets. They suggested, among other alternatives, that the nasopharyngeal secretions of influenza patients might contain something which was capable of arousing virulence in a virus normally present, in innocuous form, in the nose and throat of the ferret. Soon after the virus was first obtained an attempt to transmit influenza to human volunteers failed, but during 1936 a positive result was obtained by accident. Virus originally obtained from a human case was passed through 196 ferrets in series and was used to infect a batch of ferrets. One of these sneezed violently while being examined by Dr. Stuart-Harris. After forty-five hours a sharp and typical attack of influenza began. Washings from his nasopharynx up to the fourth day were infective both to ferrets and to mice (the first instance in which the latter were directly infected from man). Fortunately a sample of the blood serum of Dr. Stuart-Harris, taken before the attack, was available. This contained no antibody for the virus of human influenza. But there were indications of such antibody early in the attack and by the eighth day, when the symptoms had completely subsided, it was strongly developed and remained so up to the thirty-first day, after which it slowly declined. The production from the virus of a vaccine that will immunize man against influenza is now being intensively studied at the institute.

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER

Puerperal fever due to hemolytic streptococci has been responsible for the deaths annually in this country of 1,200 women in full vigor of life. Two papers published by Dr. Leonard Colebrooke and his colleagues at Queen Charlotte's Hospital, London, strongly suggest that red prontosil (4-sulfonamido-2-4-diaminoazobenzene) has a beneficial action on the infection, although more clinical and laboratory tests are necessary. An additional reason for delaying judgment is that even better results are promised with the colorless substance para-aminobenzene sulfonamide, which is the chemical mother substance of red prontosil. The following figures are instructive. During 1931-1935, 495 patients with puerperal sepsis were admitted to Queen Charlotte's Hospital, of whom 112 died, giving a mortality of 22.7 per cent. In part of 1936, sixty-four cases of puerperal sepsis were treated with red prontosil and "prontosil soluble," of which only three were fatal, a mortality of 4.7 per cent. Apart from the reduction of mortality Dr. Colebrooke has observed two changes for which these chemotherapeutic agents may be responsible. The first is a sudden reduction in the severity of the peritonitis in the cases so treated. As peritonitis has always been regarded as the most dangerous complication, the question arises of the action of the drug. The second change is that no patient has developed a palpable pelvic or abdominopelvic inflammatory mass or abscess after the beginning of the treatment, although this is one of the commonest complications of puerperal infection by hemolytic streptococci. One reason for caution in claiming success for the treatment has been advanced by Colebrooke. There are signs of a general diminution in the severity of puerperal sepsis in this country during the past five years. It is pointed out that we ought not to rely in the first place on curative drugs but on prevention, for which modern investigation suggests two lines. Access of pathogenic organisms to the birth canal must be excluded, especially streptococci associated with sore throat, whether of medical attendants, friends or the patients themselves. Prevention of their transport from the skin or other parts of the body is equally neces-

sary. Secondly, the diet of the pregnant woman should be such as to raise resistance to infection to the highest possible level, by ample consumption of milk, green vegetables and other protective foods.

The Civilian Anti-Gas School

Twenty-nine members of Parliament visited the Civilian Anti-Gas School in Gloucestershire, which is at present the only one of its kind in Great Britain. Another is to be opened soon in Yorkshire. Since the school was opened in April 1936 more than 800 persons, including police, physicians, members of the Red Cross Society and employees of local authorities, have received a fortnight's training in identifying and dealing with various poison gases and in decontamination of affected areas and clothing. They have returned to their own districts to pass on the instruction to others. It is estimated that 35,000 persons in various parts of the country are already proficient in the work of air raid precautions.

In the lecture room of the school the characteristics of the various gases and their effects were explained by Major F. W. Ollis, the chief instructor, with the aid of diagrams and lantern slides. The party was able to test for themselves the efficacy of the civilian respirators in an atmosphere charged with chlorine. Gum boots and blue glasses, for protection of the eyes against the glare of bursting incendiary bombs with a candle power of more than 50,000, were issued. On the outdoor range they were given further demonstrations of gases, high explosives and bombs containing a liquid simulating mustard gas, which gave off a pungent but harmless odor. A bomb was exploded, producing gas which spread over a large area, the cleansing and decontamination of which was demonstrated. This demonstration is only one more example of the thoroughness of the preparations that are being made against air attacks on this country.

A Difficult Social Insurance Problem

Every worker in France is obliged to be insured, according to the social insurance law, who annually earns up to 18,000 francs (\$900). This limit rises to 20,000 francs if the insured has one child less than 16 years of age, to 22,000 francs if he has two, and to 25,000 if he has three children less than 16 years old. An "indigent insured" is a worker who, although insured, has insufficient means to pay for medical care and is then placed on the relief roll of his "collectivity" (city, town). An insured worker ordinarily is obliged to pay all medical costs directly. He then receives illness certificates from the attending physician and the druggist and is reimbursed to the extent of 80 per cent of the outlay by the local caisse or office of the social insurance organization to which he belongs. In the case of an indigent insured, the local relief office pays in full the attending physician's, druggist's and other bills. Up to the present, this local relief bureau has been willing to assume only 20 per cent as its share of medical care of the indigent insured and has maintained that the social insurance local office or caisse should pay the remaining 80 per cent.

The class indigent insured (*assurés sociaux notoirement indigènes*) was created in the first social insurance act of 1928-1930 and included as such in the recently modified (October 1935) law. This category of indigent insured was defined as "ordinary social insured workers, whose resources are such as to need assistance in case of sickness." Such individuals are then (1) salaried workers obliged to be affiliated to the social insurance law, paying as such the same premiums as other insured workers, and (2) indigents entitled to free medical

care and listed as such on the rolls of their local relief bureau. All of the administrative difficulty concerning such indigent insured has been to know which of the two agencies (social insurance or local relief organizations) should be responsible for their medical care. Ought they to be treated as ordinary insured or as indigents entitled to free medical care? In the former case the attending physician could hold the insured responsible for services and was not obliged to sign the sickness certificate until being paid by the insured worker, who in turn was reimbursed by the social insurance bureau. In the case of the indigent insured, the attending physician was not allowed to present a bill for his services to the sick worker but filed a claim with the local relief bureau, which would pay the bill according to a fee table which differed considerably from that of the social insurance office. Now, in addition to this difference, the regulations of the local relief bureau vary also with respect to the number of visits allowed for a given illness, special care or radiography. The paragraph relating to this question of which organization (social insurance or relief) was responsible was not clear in either the original (1928) or the modified (1935) law.

As the result of recent decisions the indigent insured is considered an insured individual and as such is subject to all the obligations of the social insurance law but conserves all its privileges. He is hence considered as an ordinary insured worker, except that as an indigent he is not obliged to pay for medical care. The attending physician is paid directly by the local relief bureau, which in turn is reimbursed to the extent of 80 per cent of such fees by the local social insurance caisse or office. Under ordinary conditions, that is, in the case of nonindigent insured, this 80 per cent represents the sum reimbursed to the insured for medical outlays. The physician's fees will be based on the fee table of the social insurance organization and not on that of the local relief bureau. Thus the indigent insured is considered in the same category as the nonindigent insured, except that the fees for medical care are paid to the extent of 20 per cent by the local relief bureau and 80 per cent by the caisses.

Anuric Form of Hodgkin's Disease

Renal complications in Hodgkin's disease are rare; hence the report of a case of recurrent anuria as a complication as presented by Duvoir and associates at the Dec. 4, 1936, meeting of the Société médicale des hôpitaux is of considerable interest. A woman, aged 33, was admitted June 4 to the service of Duvoir because of an anuria of twenty-four hours' duration, preceded for several days by a mild rise of temperature, swelling of the inguinal lymph nodes and slight edema round the ankle joints, but no pain. There was an absence of a history of chronic nephritis and of the ingestion of any drug that could have been followed by anuria. Examination revealed the presence of a generalized adenopathy involving the regional superficial lymph nodes almost exclusively and those of the thorax or abdomen a little. The spleen was enlarged and firm. On questioning the patient it was learned that she had been given irradiation during the preceding three years for Hodgkin's disease. The hematologic formula was that of a chronic neutrophil polynucleosis. The blood urea content was 155 mg. per hundred cubic centimeters at the time of admission. Only 20 cc. of urine could be obtained on catheterization, and it showed a trace of albumin but no casts or light refracting bodies.

Based on the history of irradiation for Hodgkin's disease and the presence of generalized adenopathy, the anuria was believed to be related to the preexisting malignant lymphogranulomatosis. In spite of the administration of dextrose solutions, diuretics and high voltage roentgen therapy over the lumbar regions, uremic symptoms appeared four days after admission but receded after continuation of the irradiation and

reestablishment of the urinary secretion. The patient was discharged July 6 but returned August 3 because of a recurrence of the anuria of thirty-six hours' duration. The blood examination gave similar results to those on admission in June. Irradiation of the lumbar regions, without any other treatment, was followed after an interval of forty-eight hours by ample urinary secretion, but twenty-four hours later the anuria reappeared but lasted only a day, followed by a polyuria and apparent recovery.

This is the first report of a case of anuria during the course of a malignant lymphogranulomatosis, although transitory albuminuria and marked edema have been reported by Ziegler, Clement, Crouzon and Stoerk. The authors believed that there were two possible mechanisms to explain the anuria, either compression of the renal pedicles by enlarged lymph nodes or lymphogranulomatous infiltration of the renal parenchyma. Proof is still lacking as to which of these two to accept as an explanation of the anuria.

Chronic Nephritis in Children with Disturbances of Growth

Two interesting cases illustrating how chronic nephritis can retard development were reported at the January 8 meeting of the Société médicale des hôpitaux by Debré and his associates. The clinical symptoms polydipsia, polyuria, disturbance of glucide metabolism and arrest of development were all latent. The latency of the nephritis was so marked that over a period of several years frequent urinalyses failed to reveal the presence of albumin and the blood pressure was always found normal. The striking feature of the polydipsia was that it was the principal symptom and thus rendered difficult a differential diagnosis from diabetes insipidus in children. This was the diagnosis when the two patients were first seen. The disturbance in glucide metabolism in one of the children assumed the form of a slight intermittent glycosuria with a blood sugar quite similar to that found in diabetes mellitus. The retardation in growth was also very striking in both children. The chief and constant characteristics of certain forms of chronic nephritis in children are, therefore, dwarfism, polydipsia and polyuria. Other less constant features are disturbances in the metabolism of glucides and lipoids as well as late rachitis and at times calcinosis. The clinical picture as a whole represents some form of endocrine disturbance, pointing probably to the hypophyseal origin of the nephritis.

Second International Gastro-Enterologic Congress

The second International Gastro-Enterologic Congress will be held in Paris September 13-15 during the Exposition. The president is Prof. Pierre Duval. The two questions to be discussed are (1) the early diagnosis of gastric cancer (papers by Duval, Gosset, Carnot, Gutmann, Moutier, Garin, Labbé, Bertrand, Gatellier and Charrier of France and Konjetzny, Katsch, Sauerbruch, Buerger, Berg, Henning and Staemmler of Germany) and (2) acute and chronic obstruction of the small intestine (papers by Mogena of Spain, Wilkie of Great Britain, Bottin of Belgium, Krynski of Poland and Felsen of the United States). Only members of the International Society of Gastro-Enterology can take part in discussions.

The International Congress on Hepatic Insufficiency will follow on September 16 and will be held at Vichy. Professor Loeper of Paris is the president of this congress.

Laboratory Diagnosis of Undulant Fever

In the Dec. 5, 1936, issue of the *Progrès médicale* Lisbonne of Montpellier states that undulant fever has been found in sixty-four of the eighty-six departments of France. On account of the protean character of the symptoms, the diagnosis is not easy. Recognition of the causative organism by means of blood cultures is of great aid to the public health officer but

even in the most favorable cases requires from eight to ten days, at times even longer, and may prove to be negative in chronic cases. Nevertheless it should be employed as a routine measure at the onset of the disease. The most practical method of diagnosis is agglutination. It can be carried out in various dilutions. A total agglutination with a minimal dilution of 1 in 80 indicates a very active Brucella infection of recent origin. The intensity of the reaction increases progressively in proportion to that of the disease. Wright's serodiagnostic method is often doubtful and may be negative. The Burnet intradermal reaction is a very sensitive method but the long duration of the allergy throws no light on whether the infection is an acute one or is passive and extinct. All these methods are complementary and hence should be used in every case.

International Congress on Artificial Fever Therapy

The following French physicians will take part in the International Congress on Artificial Fever Therapy, which is to be held in New York March 29-31. Their subjects are pyrotherapy, by Professor Abrami; dosage of the temperature, by Prof. Charles Richet; physiology of artificial fever, by Professor Binet; experimental pathology, by Professors Levaditi and Bessemans; artificial fever therapy in psychiatry, by Professor Claude; in syphilis, by Professor Gougerot; in cardiology, by Professor Laubry; in surgery, by Professor Lardennois; in gynecology, by Dr. Dalsace; in ophthalmology, by Dr. Hambresin; in otorhinolaryngology, by Dr. Le Mée; in gonorrheal disorders, by Drs. Janet and Dreyfus.

Dr. Simon Flexner Elected Nonresident Member of Academy

One of the highest honors that can be bestowed on a research worker here is to be elected a French or foreign member of the Academy of Sciences of France. This recognition of the many contributions to microbiology made by Dr. Simon Flexner of the Rockefeller Institute of New York took the form of his election as a nonresident member of the Academy of Sciences at a recent meeting of that body.

The Growth of the Sick Insurance Societies

Statistics were published recently on the activities of the sick insurance during the year 1935 (THE JOURNAL, June 27, 1936, p. 2250; Jan. 16, 1937, p. 218). The legally constituted sick insurance societies administered sick benefits in a total of 52,300,000 cases (including dental cases) in 1935. In 34,800,000 instances the patients were the members themselves, in 17,500,000 the patient's relatives. Contrasted with 1934, these figures represent increases of 2,800,000 cases and 2,600,000 cases respectively. For each hundred insured persons there were 185 cases involving members themselves (5.1 per cent more than in 1934) and in addition ninety-three cases involving relatives (an increase of 13.2 per cent). The increase in illness among members as against the previous year is manifestly attributable first of all to the reemployment of older persons and to the greater speeding up of industry. The number of cases involving workers' disabilities increased at a relatively greater rate as against 1934 than the rate of increase of the total number of insurance cases. This is in part due to the fact that working conditions have permanently improved, for in bad times the worker fears that he will not be reemployed if he claims disability, and in part to the influenza epidemic, which in 1935 was more widespread than that of 1934. In each 4.6 cases in which sick benefits were received, one was connected with loss of working capability (in 1934 the propor-

tion was one in each four). The average duration of disability was, however, shorter than in the previous year.

From all the sick insurance, 8,000,000 cases involving loss of working capability were reported in 1935 (against 6,800,000 cases in 1934) and 184,500,000 working days were lost through disability (against 167,400,000 days in 1934); in other words, the number of such cases increased by 18 per cent and the number of days by 10.2 per cent compared with the previous year. The average period of disabling illness declined from 24.6 days in 1934 to 23 days in 1935. For each hundred members there were 38.5 cases of disability and 883.5 days lost through disability, as against 33.9 cases and 833.3 days in 1934. The number of women who received sick benefits was considerably greater than the number of men. As in 1934, however, cases of worker's disability were less frequent among women than among men although, to be sure, the individual illnesses of women were of longer duration so that the number of days of disability, as in the previous year, was greater for the women than for the men. In 1936 the insurance societies were once more able to balance their budgets and in contrast with previous years closed their books without a deficit. The progressive increase in the number of persons employed has brought to the insurance societies in 1936 a further important increase in membership. The average membership (exclusive of the so-called supplementary societies) amounted in 1936 to 19,500,000 persons, or 700,000 more than in 1935 and 2,500,000 more than in 1933. There were a total of 21,400,000 persons insured by the societies; this includes 2,000,000 members of the supplementary societies.

More marked than the increased membership was the increase in income, chiefly because of the increased earnings of workers. The gross income in 1936 amounted to 1,317,000,000 marks,

Growth of Sick Insurance

	1885	1934
Number of insured.....	4,700,000	18,000,000
Insured per 100 of population	10 per cent	30.4 per cent
Average duration of loss of working capability	14.2 days	24.6 days
Sick days with loss of working capacity per 100 of insured	571	902
Disbursements	57,900,000 marks	1,141,000,000 marks
Amount expended for care of the sick (including medication) per 100 marks of gross income	40.1 marks	60.8 marks
Amount expended in cash benefits per 100 marks of gross income	49.8 marks	20.6 marks
Amount expended for administration per 100 marks of gross income	6.3 marks	9.5 marks

which was 7.7 per cent more than in 1935. The costs of the individual persons receiving sick benefits remained below those of 1935, apparently because the individual illnesses ran in general milder courses than in the previous year. Altogether 8,500,000 sick persons incapacitated for work were recorded by the sick insurance (not including the supplementary societies) in 1936; 40.9 per cent of the members were deprived of working capability by illness, against 39.9 per cent in 1935. For the same reasons, despite the greater number of claims, the total expenditures increased only proportionately, that is, by 1,308,000 marks (2 per cent). Reckoned according to individual members, the gross income increased by 3.9 per cent and the contributions paid in by 6 per cent, whereas the benefits declined from 68.28 to 61.17 marks. In spite of a heavy financial burden imposed by the influenza epidemic in the last two months of 1936, the sick insurance societies (on the whole) closed their records for that year with a small surplus of about 9,000,000 marks.

Interesting too is an observation made by Dr. Grünwald, director of sick insurance affairs for the present national ministry of labor. Two concepts, he says, have from year to year become more deeply rooted in the insurance societies: the greater importance of the prophylactic as opposed to the purely therapeutic approach to disease, and the need for a fundamental eradication of incipient disease. It used to be that these principles, partially as a consequence of the poor financial condition of many societies, did not receive sufficient practical application. As it has come to be recognized that "debilitating diseases," namely, those which cause premature depletion of the energies, constitute the most serious menace to the worker's health, the demand for early treatment has increased and it becomes perceptible that from the standpoint of sick insurance the allowance for early treatment will prove less expensive in the long run than the granting of compensation solely for legally prescribed disease conditions in the individual case.

A few comparative figures that were published a short time ago on the occasion of the fifty-year jubilee of the sick insurance are reproduced in the accompanying table to illustrate the growth of this field.

RIO DE JANEIRO

(From Our Regular Correspondent)

Feb. 15, 1937.

Treatment of Cranial Trauma

Prof. Enjolras Vampré, in a lecture recently delivered to the Sociedade de Medicina e Chirurgia of São Paulo, reviewed the diagnosis and treatment of cranial trauma. When no history is obtainable, as when a patient arrives in an ambulance, the differential diagnosis is made between cranial trauma and Bright's disease, diabetes, hemorrhages, softening of the brain, convulsions, epilepsy, alcoholic coma and lethargic encephalitis. Careful examination and consideration should be given to the pulse, the arterial pressure, respiration, temperature and the reflexes. The condition of the pupils and of the fundus of the eyes is of importance. The speaker discussed the diagnostic value of ecchymoses, hemorrhages of the nose, mouth and ear, x-ray studies of the head, the integrity of the cerebral substance or its coming through a fracture, and the presence of traumatic meningo-encephalitis. Functional disturbances after trauma, showing alterations in the brain, are of more clinical importance than cranial fracture. Cranial trauma disturbs the vasomotor functions of the brain with consequent alterations of the cerebrospinal fluid and of the cerebral arteries and veins. The treatment of concussion is in accordance with the type (congestive, edematous and hypertrophic) of concussion. Immediate manometric determinations of the pressure of the cerebrospinal fluid, especially for diagnosis of suboccipital functions, are of value as, according to Leriche, there may be hypotension or hypertension of the fluid after trauma.

Ventriculography in the Localization of Intracranial Tumors

Dr. Carlos Gama recently lectured before the Sociedade de Medicina e Chirurgia of São Paulo. He reviewed the techniques of ventriculography, especially Dandy's technic for puncture of the posterior horns of the lateral ventricle. From the point of view of ventriculography, the lateral ventricles can be considered as dilated spaces, in comparison to the size of the other ventricles of the brain, which are of an irregular narrow shape, except in hydrocephalus. Certain contrast substances (such as thorium dioxide sol), which are soluble in the cerebrospinal fluid, are inconvenient in ventriculography and their use should be discontinued.

ITALY

(From Our Regular Correspondent)

Feb. 20, 1937.

National Harm from Venereal Diseases

The problem of the harm caused in Italy from syphilis and gonorrhea, from demographic, social and economic angles, was discussed at the National Congress of Dermatology and Syphilography, which was recently held at Rome. Professors De Amicis of Naples and Serra and Revelloni of Cagliari were speakers. The most important conclusions drawn were as follows: The actual number of syphilitic patients in Italy is about 750,000. Two thirds of this number are men. The annual mortality from acquired syphilis is about 30,000 deaths. That from congenital syphilis (prenatal and postnatal deaths) is about 30,000. The number of mental defectives from congenital syphilis is about 10,000. There is an annual loss of about 50,000 births due to lack of virility of men or to sterility of women from gonorrhea. In all, about 120,000 lives are lost. The social harm and economic expenses may be evaluated in an annual total loss of about 500,000,000 lire (\$25,000,000) plus other expenses in controlling diseases that develop or are aggravated by syphilis or gonorrhea. The Italian government spends about 7,000,000 lire (\$350,000) a year in preventing the development of venereal diseases.

Meeting of Obstetric Society

The annual meeting of the Società di Ostetricia e Ginecologia of Rome was recently held at Milan and presided over by Professor Alfieri, head of the clinic of the Milan University. Professor Delle Piane of Novara presented the first topic, "Cancer of the Body of the Uterus." The frequency of the latter, in comparison with other gynecologic diseases, is 0.5 per thousand, whereas in comparison with cancer of the genitalia it is 10 per cent. The average age of development of the disease is between 48 and 50 years. In 65 per cent of the cases it develops after the menopause. Benign adenoma is the most important precancerous tumor, which may become cancerous or occur in association with cancer. The mechanism of propagation of cancer of the body to the uterus and outside the structure is different from that of cancer of the neck of the uterus. The external orifice of the uterus presents an obstacle to the superficial propagation of cancer of the body, which slowly spreads to deeper layers in the uterus and outside the structure. Sometimes it extends to retrograde structures by means of metastases through the lymph vessels and the veins. The modifications of different segments of the uterus, hemorrhages and pain are important symptoms. Hysterometry, hysterography, digital examination and especially biopsy are of diagnostic value. It is advisable to apply biopsy by aspiration for early diagnosis, followed immediately by operation or physical treatment. Cancer of the body of the uterus at the time when a clinical diagnosis is made is operable in from 60 to 100 per cent of the cases. The high percentage of operability depends on the slow evolution of this type of cancer, in which the tumor is in the uterus for a long time. The treatment is excision of the uterus and the adnexa.

In the discussion, Professor Artom of Rome called the attention of general physicians to the diagnostic importance of cancer of the body of the uterus and to the need of examining the entire structure and not merely the neck. Professor Zancola of Palermo reported satisfactory results from the roentgen treatment in nineteen of twenty-three patients who had cancer of the body of the uterus. Professor Maurizio of Padua reported results from the roentgen treatment in about 405 cases of cancer of the uterus in which treatment was administered at the clinic of the University of Padua from 1928 up to the present time. There were no deaths in the group of forty-eight patients who suffered from cancer of the body of the uterus. Professor Momigliano of Rome said that diabetic

patients who suffer from cancer of the body of the uterus have to be given insulin before irradiation because radium and the x-rays increase glycemia. Professor Alfieri of Milan is opposed to irradiation. He advises total hysterectomy, except in cases in which contraindications exist. In cases of cancer of the body that were treated by the speaker with liberal doses of radium (70 millicuries) the hemorrhage was controlled, but neoplastic tissue was found in the uterus several months later.

The second topic was glycosuria and diabetes with relation to maternity. Professor Bompiani of Palermo was the speaker. Glycosuria in the course of pregnancy may originate in a lowering of the renal threshold, in a paradiabetic condition in association with or independent of lowering of the renal threshold, and in diabetes. Sometimes diabetes is latent and shows itself by a condition of relative insufficiency of the insular system which is due to endocrine changes induced by pregnancy. In the origin and evolution of glycosuria the functional activity of the anterior lobe of the hypophysis is of the utmost importance because of the relations of the lobe to the metabolism of pregnant women and the rôle of functional hypophyseal disturbances in the development of pathologic conditions in pregnancy. The speaker discussed the advisability of permitting conception or inducing sterility in diabetic women, the influence of diabetes on pregnancy, labor, the puerperium and lactation, and the influence of maternity, the evolution and the complications of diabetes.

Personal Items

Prof. Luigi Auricchio has been appointed professor in the pediatric clinic of the University of Naples to succeed Prof. Rocco Jemma, who resigned because he reached the age limit for teaching (70 years). Professor Auricchio has reported results of clinical work on several pathologic conditions, especially the pathogenic and diagnostic aspects. His most important contributions are on hemorrhagic diatheses, eosinophilia, varicella, vaccination and serodiagnosis of infantile leishmaniasis.

Course on Industrial Medicine

A course on specialization in industrial medicine will be given at the Ospedali riuniti di Pistoia. The motion for establishing the course came from the Accademia Medica Filippo Pacini. The course will cover industrial medicine from the point of view of Italian industrial laws, both those now in force and those which will come into force April 1.

Serotherapy Institute in Addis Ababa

A branch of the Milan serotherapy institute will be open at Addis Ababa in the near future. The construction of the building was recently begun.

Marriages

CLIFFORD MCKINLEY CRESWELL, New York, to Miss Dorothy Summer Beaman of Providence, R. I., Dec. 19, 1936.

B. KIRTLEY AMOS, Princeton, Ky., to Miss Delia Elizabeth Godley in Washington, N. C., March 17.

ROMUS ARNOLD, Joliet, Ill., to Mrs. John Edgar Brock of Evanston in Lansing, Mich., in March.

CHALMERS E. CORNELIUS, Jenkintown, Pa., to Miss Elizabeth Oelbermann of Philadelphia, April 3.

JOSEPH BUCKNER KILLEBREW to Miss Katherine Bessent, both of Chattanooga, Tenn., January 10.

LESLIE D. DARNER to Miss Lucie Demery, both of Granite City, Ill., in Palmer, March 28.

JAMES BELL CAROTHERS to Mrs. Jane Brown Daniel, both of Atlanta, Ga., January 9.

FLOYD M. BURGESSON to Miss Helen Anderson, both of Atlanta, Ga., February 18.

ROBERT D. CRAWFORD, Dothan, Ala., to Miss Tommie Cotter in Ozark, January 12.

Deaths

Thomas J. Gallaher * Denver; University of Pennsylvania Department of Medicine, Philadelphia, 1889; secretary of the Section on Laryngology and Otology of the American Medical Association, 1894-1895; professor of laryngology and rhinology at the University of Denver Medical Department, 1897-1902; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; on the staffs of St. Luke's and Children's hospitals; for two years member of the medical advisory board of the Presbyterian Hospital; aged 69; died, February 5, of angina pectoris.

Philip Hammond, Boston; Harvard University Medical School, Boston, 1894; member of the Massachusetts Medical Society, the American Otological Society and the New England Otological and Laryngological Society; for many years instructor in otology at his alma mater; consulting aurist for the Massachusetts General Hospital, the Massachusetts Eye and Ear Infirmary, the Melrose (Mass.) Hospital, Winchester (Mass.) Hospital, the Anna Jacques Hospital, Newburyport, and the Hale Hospital, Haverhill; aged 65; died, February 7, of Hodgkin's disease.

Alfred Schalek, Omaha; German University of Prague, Austria, 1890; professor emeritus of dermatology and syphilology, University of Nebraska College of Medicine; formerly assistant professor of skin and venereal diseases at Rush Medical College, Chicago; member of the American Dermatological Association; past president of the Omaha Dermatological Society; member of the staffs of the Methodist, Immanuel and Swedish hospitals; author of "Diseases of the Skin" and "Fundamentals of Dermatology"; aged 71; died, February 9, of pneumonia.

Edwin Elgin Evans * Columbia, Mo.; University of Missouri School of Medicine, Columbia, 1898; member of the American Psychiatric Association; at various times assistant physician, State Hospital, Fulton, State Hospital, St. Joseph, superintendent of the East Louisiana State Hospital, Jackson; assistant superintendent and managing officer of the Huntington (W. Va.) State Hospital; aged 68; died, February 8, in St. Louis, of coronary thrombosis.

James Harrison Hodges, Gainesville, Fla.; College of Physicians and Surgeons, Baltimore, 1888; member and past president of the Florida Medical Association; formerly member of the state board of medical examiners; at one time superintendent of the Florida Farm Colony for Epileptic and Feeble-minded; served as a physician for the Seaboard Air Line Railway and the Atlantic Coast Line Railroad for many years; aged 70; died, February 3.

William Edgar Holland, Fayetteville, Pa.; Medical-Chirurgical College of Philadelphia, 1891; member of the Medical Society of the State of Pennsylvania; past president of the Franklin County Medical Society; on the staff of the Chambersburg (Pa.) Hospital; served as a school director in Greene Township and for a number of years was president of the board; aged 66; died, February 3, of chronic nephritis and uremia.

Henry Irving Cozad * Cuyahoga Falls, Ohio; Western Reserve University Medical Department, Cleveland, 1898; member of the American Psychiatric Association; formerly chairman of the county and city board of health; medical director and superintendent of the Fair Oaks Villa; aged 64; neurologist to the Akron City Hospital, where he died, February 1, of pneumonia.

Felix William Garcia, St. Louis; Washington University School of Medicine, St. Louis, 1893; at one time lecturer of anatomy at the Marion-Sims College of Medicine; for many years physician for the Home for the Aged of the Little Sisters of the Poor; aged 65; died, February 11, in the Barnes Hospital, of carcinoma of the larynx.

Herman Louis Fuerstman, Newark, N. J.; Long Island College Hospital, Brooklyn, 1910; member of the Medical Society of New Jersey; for many years a member of the board of education; on the staff of the Beth Israel Hospital; medical director of the Essex Private Hospital; aged 52; died, February 12, of coronary thrombosis.

Elphege A. René De Cotret, Montreal, Que., Canada; M.B., Laval University Medical Faculty, Montreal, in 1886, and M.D. in 1888; formerly professor of obstetrics and clinical obstetrics at the University of Montreal Faculty of Medicine; at one time one of the directors of L'Hôpital Notre-Dame; aged 75; died, February 7.

Fred Henry Shorts * Kent City, Mich.; Saginaw Valley (Mich.) Medical College, 1903; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; for many years member of the school board; veteran of the Spanish-American and World wars; aged 61; died, February 12.

Halbert Lee Waterman, Brattleboro, Vt.; University of the City of New York Medical Department, 1892; formerly member of the state board of medical registration; at one time health officer of Brattleboro; on the staff of the Brattleboro Memorial Hospital; aged 68; died, February 20, of lobar pneumonia.

Ezra Esher Fry * Bonners Ferry, Idaho; University of Toronto (Ont.) Faculty of Medicine, 1902; for many years county physician; member of the board of village trustees and school board; president of the bank; founder of the Bonners Ferry Hospital; aged 61; died, February 6, of coronary thrombosis.

William Marvin Johnson * Sparta, Tenn.; University of the South Medical Department, Sewanee, 1900; past president of the White County Medical Society; served during the World War; formerly county health officer, and member of the school board; aged 60; died, February 2, of influenza and pneumonia.

Albert Harold Linaweaver, Findlay, Ohio; College of Physicians and Surgeons of Chicago, 1896; member of the Ohio State Medical Association; past president of the Hancock County Medical Society; on the staff of the Home and Hospital; aged 80; died, February 2, of heart disease.

Theodor L. E. Arnold, Dallas, Texas; Universität Bern Medizinische Fakultät, Switzerland, 1875; Universität Zürich Medizinische Fakultät, Switzerland, 1886; member of the State Medical Association of Texas; aged 88; died, February 23, of arteriosclerosis, myocarditis and coronary sclerosis.

Helene Emeth Schutz * Ann Arbor, Mich.; University of California Medical School, San Francisco, 1927; instructor in hygiene and public health and physician in the health service, University of Michigan; aged 35; hanged herself, February 20, while a patient at a hospital in New York.

William Hirsch, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; member of the Medical Society of the State of New York; formerly consulting physician at the Manhattan State Hospital; aged 78; died, February 14.

Sylvester A. Hawes, Greenville, Ohio; Medical College of Ohio, Cincinnati, 1884; on the staff of the Greenville Hospital; for many years pension examiner in Darke County; physician and surgeon for the New York Central and Baltimore and Ohio railroads; aged 76; died, February 20.

Ernest E. Hancock * Battle Creek, Mich.; Hospital College of Medicine, Louisville, Ky., 1901; aged 62; died, February 13, in the Nichols Memorial Hospital, as the result of injuries received when the automobile in which he was driving was struck by a train.

John William Ebert * Towson, Md.; University of Maryland School of Medicine, Baltimore, 1912; on the staff of St. Joseph's Hospital, Baltimore; aged 49; was found dead, February 2, at his home in West Palm Beach, Fla., of coronary thrombosis.

William Morton De Bord, Ashland, Ky.; University of Louisville Medical Department, 1907; member of the Kentucky State Medical Association; veteran of the Spanish-American War; formerly county health officer; aged 63; died, February 17.

Oliver Perry Faires, Greenfield, Mo.; Kansas City Medical College, 1905; for many years Jackson County jail physician; aged 71; formerly on the staff of the Trinity Lutheran Hospital, Kansas City, where he died, February 9, of pneumonia.

Ernest Perry Clement, Elyria, Ohio; Starling Medical College, Columbus, 1898; member of the Ohio State Medical Association; past president of the Lorain County Medical Society; aged 62; died, February 2, of cardiorenal vascular disease.

William Rendell Williams, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1902; professor of clinical medicine at his alma mater; aged 63; died, March 5, in the Hahnemann Hospital, of carcinoma of the bladder.

Stephen Anderson Hall, Advance, Ind.; Kentucky School of Medicine, Louisville, 1894; aged 72; died, February 20, in the St. Mary and Elizabeth Hospital, Louisville, Ky., of injuries received when he was struck by an automobile.

William Martin Dummer, Fairfax, Minn.; Northwestern University Medical School, Chicago, 1918; member of the

Minnesota State Medical Association; aged 50; died, February 1, in Rochester, of hypertension and renal insufficiency.

Ernest G. Epler, Fort Smith, Ark.; Chicago Medical College, 1883; member of the Arkansas Medical Society; one of the founders and on the staff of Sparks' Memorial Hospital; aged 76; died, February 22, of carcinoma of the liver.

Adolph Lincoln Marks, St. Louis; St. Louis College of Physicians and Surgeons, 1897; also a dentist; veteran of the Spanish-American War; aged 75; died, February 3, in the Lutheran Hospital of cerebral hemorrhage.

George M. Bradish, Grand Rapids, Mich.; Eclectic Medical Institute, Cincinnati, 1879; for many years county coroner and township health officer; aged 82; died, February 22, of cerebral hemorrhage and chronic nephritis.

Frank Henry Luce, Seattle; University of the City of New York Medical Department, 1882; formerly member of the state legislature and lieutenant governor; aged 77; died, February 1, of coronary thrombosis.

John Roscoe Ash, Brighton, Ill.; Beaumont Hospital Medical College, St. Louis, 1889; member of the Illinois State Medical Society; aged 69; died, March 19, in a hospital at Alton, of pneumonia.

Merritt Fillmore Lee, Middle Grove, N. Y.; Eclectic Medical College of the City of New York, 1883; also a minister; aged 84; died, February 8, of arteriosclerotic heart disease and cardiac embolus.

Robert F. Shinsky Ⓢ Detroit; Detroit College of Medicine and Surgery, 1920; aged 49; for many years on the staff of St. Mary's Hospital, where he died, February 2, of a staphylococcal infection.

Frank Louis Darrow, Columbus Junction, Iowa; Jefferson Medical College of Philadelphia, 1882; Bellevue Hospital Medical College, New York, 1885; aged 80; died, February 13, of arteriosclerosis.

William Byrd Jackson Ⓢ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1928; aged 32; on the staff of the Mercy Hospital, where he died, February 11, of pneumonia.

Roscoe Felix Johnson, Columbus, Ga.; Baylor University College of Medicine, Dallas, Texas, 1914; served during the World War; aged 44; died suddenly, January 31, of heart disease.

William James Richardson, Greensboro, N. C.; Jefferson Medical College of Philadelphia, 1886; aged 73; died, February 17, in the Wesley Long Hospital, of chronic nephritis and myocarditis.

Harriet Louise Hawkins, Birmingham, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; aged 75; died, February 21, of arteriosclerosis and myocarditis.

August Anderson Ⓢ Chicago; Hahnemann Medical College and Hospital, Chicago, 1916; veteran of the Spanish-American and World wars; aged 55; died, March 14, of organic heart disease.

Charles Wilson Hughes, Wilmington, Del.; Pulte Medical College, Cincinnati, 1893; on the staff of the Homeopathic Hospital; aged 75; died, February 11, of acute pulmonary edema.

Oscar Landauer, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1903; aged 53; died, February 17, of illuminating gas poisoning, self administered.

Charles L. Jones, Noble, Ill.; Barnes Medical College, St. Louis, 1903; aged 62; died, February 2, at the Olney (Ill.) Sanitarium, of cardiovascular renal disease.

Harry Alonzo Huntoon, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1908; aged 56; died, February 12, of pneumonia.

Douglas Duperier, Port Arthur, Texas; Tulane University of Louisiana Medical Department, New Orleans, 1892; aged 72; died, February 9, of chronic myocarditis.

Sullivan Howard, Elk Creek, Neb.; University of Denver Medical Department, 1892; aged 71; died, February 2, in St. Petersburg, Fla., of cerebral hemorrhage.

William M. Cory, Waterville, Minn. (licensed in Minnesota under the Act of 1887); aged 78; died, February 5, of influenza, acute nephritis and uremia.

Edwin William Rose, Gladstone, Manit., Canada; Manitoba Medical College, Winnipeg, 1900; aged 59; died, February 23, of lobar pneumonia.

Correspondence

POSTGRADUATE MEDICAL EDUCATION IN VIENNA

To the Editor:—Notwithstanding the ravages of the World War and of the chaotic period that followed it, Vienna nevertheless succeeded in retaining her popularity among American physicians as a first class postgraduate medical center. During the past summer, for instance, there were approximately seventy-five English-speaking physicians constantly in attendance, and the organization which served them, the American Medical Association of Vienna (in no way connected with our own American Medical Association) boasted a life membership exceeding eight thousand, accumulated during its thirty-two years of existence.

The most plausible explanation for this enduring popularity is unquestionably the "hands-off" policy of the Austrian government, which until recently at least has been not to interfere with the intellectual and scientific pursuits of its universities. Unfortunately, however, sufficient evidence exists to indicate a gradual deviation of late from this liberal policy. Manifestations of political regimentation, such as the removal of men, even though highly competent, from university and hospital positions solely because of political or racial nonconformities, were quite obvious to Americans visiting there several months ago, and particularly to those of us who had our instructors picked before reaching Vienna. For instance, of the four names listed in my own "prospectus" I discovered on arrival that one had already been deprived of his teaching facilities and that another was expecting fearfully a similar fate in the near future. His fears have since then materialized into a tragic reality.

These facts argue for a preliminary investigation on the part of American physicians contemplating postgraduate study in Vienna. The important question to settle of course is whether or not the instructors concerned are still in their favorable teaching positions. The continued appearance of their names in the printed catalogues does not always tell the whole story. A clinician may still be listed as "dozent," for instance, and yet not have an adequate amount of clinical teaching material at his disposal.

Letters of inquiry directly to the instructors under consideration should help to do away with many of these uncertainties and should tend to obviate much of the disappointment and confusion that might otherwise result.

MAX MILLMAN, M.D., Springfield, Mass.

"THE THERAPEUTICS OF PROSTIGMIN"

To the Editor:—In the article "The Therapeutics of Prostigmin" by Drs. Goodman and Bruckner (*THE JOURNAL*, March 20) there is much cause to reflect. The patient was given 45 mg. of prostigmin orally at a single dose. This is considerably larger than the small single oral doses usually given to patients suffering from myasthenia gravis. After such a dose the subject exhibited characteristic signs of overdose (diarrhea, miosis, sweating, and so on) and there is a reasonable presumption that the patient was more than usually susceptible to the drug. The reaction described, while unpleasant, cannot be regarded as being dangerous.

I have treated six patients suffering from myasthenia gravis with aminoacetic acid, ephedrine, beta-aminopropylbenzene and other methods. In all but one case the best therapeutic effect was obtained with prostigmin given orally in amounts averaging from 60 to 120 mg. daily in single doses of 15 mg. at intervals. I have never seen any evidence of severe abdominal pain, diarrhea or other untoward symptoms in these patients. Three of the six would be bedridden were it not for the use

TREATMENT OF SYPHILIS

To the Editor:—The paper by Stokes on "Clinical Problems in Syphilis Control Today" [THE JOURNAL, March 6] is quite the most useful résumé I have ever read—clear, coherent, easily expressed. I am teaching pharmacology to fourth year medical students at Queen's University, and we have recently been studying our means of attack on this problem. The only thing I do not find sufficiently clear is the statement of the distribu-

The treatment schedule corresponding to the sloganized "30-60-0-3" is the American continuous alternating system of treatment described in the report of the Commission of Experts on Syphilis of the League of Nations Health Organization.

The week-by-week tabular presentation of this standard course of treatment is herewith reproduced.

Plan of Alternating Continuous Treatment for Early Syphilis *

Time	Arsphenamine, Gm.	Interim Treatment	Serologic Test	Comment	
Day					
1	0.3-0.6	1	Arsphenamine dosage for first 3 injections at level of 0.1 Gm. for each 25 pounds (11.3 Kg.) of body weight. Average subsequent dosage, 0.4 Gm. men, 0.3 Gm. women, the fourth and subsequent injections in the first course at weekly intervals. In average patient, all lesions heal rapidly and blood serologic reaction becomes negative during first course. If arsphenamine cannot be used, substitute 8 to 10 doses of 0.3 Gm. of silver arsphenamine or 10 to 12 doses of neoarsphenamine (0.45-0.6 Gm. maximum for women and 0.6-0.75 Gm. for men). This applies also to subsequent courses

* Table 2 in "League of Nations Investigation and Report on Treatment of Early Syphilis," by the Committee of Experts on Syphilis and Cognate Subjects, Zurich, Nov. 21-23, 1934, published in THE JOURNAL, April 13, 1935, page 1329.

tion of the drug courses—five injections of the arsenical and ten of bismuth subsalicylate over the sixty-five weeks. How are the thirty injections of the arsenical related to the sixty of bismuth subsalicylate as to time interval and rotation relationship (p. 782, line 17 and following)?

THOMAS GIBSON, M.D., Kingston, Ont.

ANSWER.—The United States Public Health Service Division of Venereal Diseases publishes the proceedings of the Conference on Venereal Disease Control held in Washington, December 1936, which includes the series here mentioned, as a separate publication.

EFFECTS OF ENDOCRINE MATERIALS ON GROWTH

To the Editor:—I have a patient, 15 years of age, nearly 6 feet (183 cm.) tall, and weighing only 125 pounds (56.7 Kg.). His bones are small and long; the penis and testicles also are small. I want to know what preparation of the glands would be best to give him to cause him to develop more normally.

A. S. EPPERSON, M.D., Cameron, Texas.

ANSWER.—The information given is inadequate to permit definite advice, since one cannot be certain from this description which glands are dysfunctioning and to what extent. Further

information regarding the endocrine status, especially of the thyroid, pituitary and gonads, is essential before embarking on therapy, and to this end it is advisable to determine the basal metabolic rate, sugar tolerance and, if practicable, hormone extraction studies for gonadal and pituitary function.

The size of the testicles occasionally increases following intramuscular injection two or three times a week of the gonadotropic principle from pregnancy urine in doses of from 100 to 200 rat units. This may be continued for two or three months. Development of the external genitals sometimes follows the administration of the recently developed synthetic testicular hormones. If the basal metabolism is depressed a thyroid deficiency is indicated, and thyroid in appropriate doses should be given.

Since the patient is evidently markedly asthenic and underweight, a diet regimen planned to increase his weight and nutrition is advisable.

For a more complete report, more detailed diagnostic study, including anthropometric measurements and bone-age pictures, is needed. Many of these cases develop spontaneously at the age of puberty and need no treatment at all.

TRAUMA AND GASTRIC ULCER

To the Editor:—A man, aged 32, while working as a warp hanger in a silk weaving mill Jan. 7, 1936, was struck with considerable force in the center of the epigastrium by the end of a shuttle, which flew off one of the looms. He became weak and faint and, in a few minutes, nauseated. About five minutes after the accident he vomited what remained of his breakfast, which he had eaten two hours before. About half an hour later he again became nauseated and vomited about half a pint of (apparently) pure blood. He was then taken to a hospital, where he remained thirteen days. The vomiting of blood continued for three days, at which time he began having cramping, abdominal pains. Since that time he has had attacks of cramping, abdominal pains lasting from three to eight hours at intervals of about one week and has lost about 15 pounds (7 Kg.). He has had no appetite. The attacks of cramping pain have been rather severe but in no case, except in the first attack, has he been given narcotics for relief. He came under my care recently but states that the only medication by mouth he has received from other physicians under whose care he has been is an alkaline powder called papsomax. The attacks of pain apparently have no connection with the ingestion of food. After finding a positive reaction for sugar in the urine, I had the blood sugar tested, which showed 143 mg. per hundred cubic centimeters of blood. The Kahn test is negative. The x-ray examination of the gastro-intestinal tract showed a punched out ulcer on the greater curvature of the stomach about a third of the way between the esophagus and the pylorus. Pressure over this point under the fluoroscope caused much pain; it was the most tender spot of the entire stomach and duodenal area, although there is tenderness over the entire stomach and duodenal area. Under the fluoroscope he pointed to a spot about half an inch above the pylorus as the point where the shuttle struck him. The patient states that he had never had any stomach trouble or abdominal complaints before the injury. His white blood cell count is 12,700, red blood cell 5,750,000, hemoglobin 90 per cent. The urinalysis showed, besides the positive Fehling test, one plus albumin, occasional pus cells and an amorphous phosphate sediment. He has never had any operations. Can there be any connection between this man's injury and his present condition? What further can be done to clear up this case and what treatment do you advise?

M.D., North Carolina.

ANSWER.—One may properly conclude that trauma was the inciting or actual causative factor to explain the presence of the gastric ulcer and the presence of disturbed carbohydrate metabolism. The latter condition is actually a form of diabetes that may be latent or subclinical or could be the direct result of pancreatic injury. The factor of trauma in the genesis of acute and chronic peptic ulcer has been a subject of contention for many years. Recent contributions to the American literature on the subject have been made by Crohn and Gerendasy, Eusterman and Mayo, and Irving Gray. Judging from the cases reported, such ulcers are more likely to occur in the stomach than in the duodenum, as a portion of the stomach underlies the exposed epigastric angle of the abdominal wall. The duodenum lies deeper and is more protected.

The nondescript nature of the abdominal pains makes it difficult to determine their origin; they are certainly not characteristic of ulcer. However, the traumatic, possibly penetrating, nature of the lesion, and the probability of an associated pancreatitis, could explain the atypical symptom complex. Lesions on the greater curvature, posterior wall or prepyloric area are often carcinomatous, but under the circumstances one would greatly discredit that possibility. It seems essential that the patient be hospitalized for a period of a month on adequate ulcer management, with a continuation of the treatment in ambulant fashion for six or eight months thereafter at least. If satisfactory improvement from both a clinical and a roentgenoscopic standpoint does not occur, surgical intervention may be advisable. If hyperglycemia persists, a certain amount of restriction of carbohydrates is also advisable.

DUPUYTREN'S CONTRACTION, ARTHRITIS OR FIBROSITIS

To the Editor:—A man, aged 63, complains of a progressive stiffness of the joints for the past eight years with little pain, involving largely the smaller joints. The phalangeal joints of the hands and feet are practically fixed and the metatarsophalangeal joints, especially of the large toes, are greatly limited. There appears to be a slight atrophy of the small muscles of the hand, the joints are not enlarged, and there is but little sensory disturbance except a rather intense burning of the right foot. Is this a form of arthritis? The reflexes appear somewhat hyperactive but the same bilaterally, and no clonus is present. The flexor tendon of the third right finger is hard as if calcified, is contracted, and is attached to the overlying skin. This firm tendon interferes with the patient's work as a carpenter and also the finger is permanently fixed at the first phalangeal joint. The left hand appears to be on the same curve as the right because the skin appears attached over the corresponding tendon in the palm and at the wrist, and motion is limited. The patient has considered having the finger on the right hand amputated. Would this be the proper procedure? Would releasing the skin and probably the tendon sheath in the left hand avoid the contracture? Please enclose name.

M.D., Pennsylvania.

ANSWER.—The case suggests the need for distinguishing three conditions from one another: (1) Dupuytren's contraction, (2) chronic arthritis with fibrositis and fasciitis producing contraction resembling the Dupuytren type, and (3) "chronic fibrous rheumatism" of Jaccoud. The report is that the skin of the hand is firmly attached to the underlying tissues ("tendons") and that there is a flexion deformity of one phalangeal joint. "Dupuytren's contraction" is a palmar fasciitis resulting from inflammatory hyperplasia or "fibroid hypertrophy" of the palmar connective tissue. The condition affects the palmar fascia and skin and its digital prolongations. The statement is often mistakenly made that tendons are involved. When the affected fingers are extended, cordlike contractions become prominent in the palm, but these are not tendons; they are the contractions of the palmar fascia. Tendons are not affected, as operations on them have shown. At first a patient so afflicted will note a feeling of tightness in the palms of the hand or in the ring (fourth) or fifth finger. Neuralgic pains may be felt and the patient cannot fully extend a finger. Careful examination may reveal one or several nodules in the palmar fascia, most commonly near the base of the fifth finger. At first the nodule is not attached to the overlying skin; later the skin becomes adherent to the hypertrophied fascia and nodule in a hard, firm attachment. Contractions occur and one or more fingers may be flexed, sometimes sharply, on the palm. The condition is usually bilateral, although it often begins in one hand, especially the right, months or years before it appears in the left hand. The cause is unknown, but trauma, infection or a "trophoneurosis" has been held responsible. Since carpenters and others who use their hands extensively are most commonly affected, trauma is regarded as the most important aggravating, predisposing or localizing factor.

Textbooks and dictionaries define Dupuytren's contraction as disorder of the palms and do not describe it as affecting the feet. The patient under consideration apparently has stiffness of the metatarsophalangeal joints as well as of the hands. No contractions in the feet are mentioned. It is possible therefore that the patient does not have "true" Dupuytren's contraction but has "false" Dupuytren's contraction, which is not infrequently seen in cases of chronic arthritis. Patients who have chronic infectious (atrophic, rheumatoid, proliferative) arthritis frequently have an accompanying fibrositis and fasciitis and, when the palmar fascia, tendons and periarticular tissues are involved, contractions resembling Dupuytren's contraction may ensue. The inflammatory reaction of the "arthritis" invades subcutaneous, fibrous and fascial tissue: nodules may form and flexion deformities and contractures of one or more fingers may result, and the overlying skin may become firmly attached to fibrotic fascia as in true Dupuytren's contraction. The inquirer has not mentioned whether roentgenograms of the joints, flexed and otherwise, gave evidence of intra-articular as well as of periarticular disease. In chronic infectious arthritis, with or without contraction resembling the Dupuytren type, the sedimentation rate of the erythrocytes is practically always elevated (generally above 30 mm. at the end of one hour), and secondary hypochromic anemia and loss of weight are generally present. No studies on the sedimentation rate of the erythrocytes in Dupuytren's contraction seem available, but in cases of local or general fibrositis without arthritis the sedimentation rates are normal or but slightly elevated (less than 30 mm.) and one would expect rates to be normal in true Dupuytren's contraction, which is essentially a special form of fibrositis.

A rare and rather "malignant" form of fibrositis must also be considered: Jaccoud's fibrositis, or "rhumatisme chronique fibreux." In this disease many joints are involved in an "inveterate and aggravated form of fibrositis," which involves

not only periarticular tissues but also related tendon sheaths and aponeuroses. Many joints may be affected. Although deviations and subluxations may result from the marked contraction of cicatricial tissues, no actual arthritis is present even in joints that are inexorably fixed and seemingly ankylosed. No hypertrophic or osteophytic outgrowths of bone occur, and cartilage surfaces are normal even in the face of "pseudo-ankylosis." Contraction resembling the Dupuytren form may develop and because of the malpositions and apparent ankyloses the condition closely resembles the deformities of chronic infectious arthritis with which it was confused before Jaccoud's time.

The exact clinical relationships and differences between these three conditions—the fasciitis and contractions of true Dupuytren's disease, those of chronic infectious arthritis, and those of Jaccoud's rheumatism—have not been determined, but pathologically the three conditions seem to be closely related.

The patient should have treatment for the general disease (arthritis or fibrositis) and for the local condition in the hand. Removal of foci of infection seems rational but the patient's occupation, carpentry, suggests that the chronic trauma therefrom may have been at least an aggravating or localizing factor as far as the hands are concerned, although of course his occupation does not explain the involvement of the feet. Physical therapy and massage are indicated, but the condition may be too far advanced for relief to result. Various forms of surgical and nonsurgical therapy for such palmar contractures and flexions of fingers were described by Tubby. In a recent report, Meyerding surveyed the clinical features of Dupuytren's contraction affecting 448 hands of 273 patients. The pathologic condition was described and the technic of his operation was detailed. The most successful treatment was found to be removal of the contracting palmar fascia. Occasionally it seemed best to disarticulate and amputate part of a badly flexed finger and to use the skin of the finger as a pedicle graft. Often, however, correction of flexed fingers was accomplished by fascial resection without amputation.

BLOOD IN SPINAL FLUID

To the Editor:—1. In the presence of a skull injury, is there any way of differentiating a bloody spinal fluid from an accidental bloody tap? 2. How long after bleeding into the subarachnoid space does xanthochromia develop? 3. If, in doing a spinal tap, there is accidental injury to a vein, how long afterward can one expect to find blood in the spinal fluid? 4. Will xanthochromia develop in the spinal fluid in such a case? In the case in question, a spinal tap thirty-six hours after head injury brought forth a markedly bloody fluid. On standing, a clump of blood cells settled to the bottom of the test tube, leaving a perfectly clear supernatant fluid. Two days later a second tap gave a hazy spinal fluid, which on microscopic examination proved to be due to red blood cells. Does this indicate that the blood in the spinal fluid was due to the head injury or might the blood in the second tap have been due to the trauma of the first tap? Please omit name. M.D., Pennsylvania.

ANSWER.—1. There is no absolute criterion for differentiating blood due to intracranial hemorrhage from that due to puncture trauma. The following points, however, may aid in the differentiation:

In puncture trauma the fluid becomes progressively clearer as it continues to flow out from the needle, while in intracranial hemorrhage the blood in the fluid is evenly distributed. In intracranial hemorrhage, minute clots may be present in the cerebrospinal fluid.

As a rule the blood clots on standing in puncture trauma while in intracranial hemorrhage it usually does not clot.

In puncture trauma the supernatant fluid is clear; in intracranial hemorrhage the supernatant fluid is xanthochromic.

The benzidine test on the supernatant fluid is usually negative in puncture trauma and positive in bloody fluid due to intracranial hemorrhage.

In intracranial hemorrhage, crenated cells are usually present in large numbers.

2. Xanthochromia usually begins to develop within a few hours after the onset of bleeding in the subarachnoid space and increases in intensity for the next few days.

3. Grossly the blood in the fluid due to traumatic puncture begins to diminish within a few hours. Haziness of the fluid usually persists for three or four days. Microscopic evidence of blood may persist even longer.

4. Xanthochromia does develop following a traumatic puncture unless a very small amount of blood was present to begin with.

5. In the case in question, the fact that a clump of cells settled in the bottom leaving a perfectly clear supernatant fluid speaks for the blood having been due to a traumatic spinal puncture. The hazy spinal fluid on the second puncture was most likely due to the residue from the original bloody puncture.

PERSISTENT ENURESIS IN BOY EIGHTEEN YEARS OLD

To the Editor:—An intelligent boy of 18 has always had nocturnal enuresis. It fails to respond to treatment. The enuresis may occur two or more nights in succession. Seldom has an interval of eight days passed without such an occurrence. The urine is normal. The basal metabolism rate was minus 7. The history and examination seem to show the condition purely functional. Reasonable trial of the following have made but little, if any, impression: (1) limitation of afternoon and evening fluid intake; (2) thyroid from 3 to 5 grains (0.2 to 0.3 Gm.) daily to physiologic symptoms of warmth and flushed skin; (3) whole pituitary orally, 12 grains (0.8 Gm.) daily; (4) twice weekly injections of from 1 to 2 cc. of antuitrin-S; (5) instillation in the nose on retiring of posterior pituitary powder or of postpituitary jelly; (6) injections of postpituitary 1 cc. each; (7) ephedrine hydrochloride three-fourths grain (0.05 Gm.) at bedtime to increase in a like amount every four to seven days (see R. W. Brookfield's article in the *Lancet*, Nov. 16, 1935). Atropine in increasing doses has not yet been used because in the beginning of treatment it was my belief that antuitrin-S might develop more growth in the prostatic region and produce a desired tone to the bladder sphincter and thus the condition be permanently overcome. Having failed in the use of the various gland products, I am now considering other measures. If one lessens the depth of sleep by benzedrine sulfate or ephedrine is it not reasonable to think that the desire to urinate might awaken one? I would appreciate your suggestions for continued or different treatment.

LEE W. PAUL, M.D., Los Angeles.

ANSWER.—The most difficult cases of enuresis to treat are those of long standing in older children. It is rare for this condition to continue beyond the age of puberty unless there is an organic cause as the basis for the symptom. The age of the patient is 18 years. The treatment of the condition with drugs is at least disappointing. In the case in question, before advocating any further drug treatment, it would seem essential to investigate some underlying organic cause. Among the more common causes of paralysis of the bladder are spina bifida, either of the external or of the occult type, neoplasm of the cord, and transverse myelitis following infectious disease. Other organic conditions that might cause enuresis are foreign body in the bladder, kidney calculus, renal embolism or thrombosis, and congenital malformation. In order to rule out these conditions, x-ray examination of the spine and genito-urinary tract would be indicated, as well as a complete neurologic examination, and finally, if these are entirely negative, an instrumental urologic examination would seem warranted. If these tests satisfactorily rule out any organic reason for the enuresis, psychologic investigation and therapy would seem preferable to further drug or endocrine treatment.

TAPEWORM

To the Editor:—Somewhere, sometime, I noticed a statement made that if a protruding section should be injected with some medicament, it would cause the head of a tapeworm to loosen so it could be expelled. I have recently had a couple of cases of beef tapeworm and find it quite difficult with the routine treatment to get the head, and if it is possible by injecting the terminal segment with anything, it might be a help. What was the medicament used? J. W. SEIDS, M.D., Moline, Ill.

ANSWER.—There is no drug that will cause the expulsion of the entire tapeworm by injection of the terminal segment. The scolex or head of the cestodes or tapeworms has from two to four suckers and may be provided also with clawlike curved hooks. The tapeworm thus fastens itself to the intestinal wall.

Taenia saginata, the beef tapeworm, has a head about 2 mm. wide and has a flat crown and four large suckers. This worm may have from 200 to 450 segments and is often from 2 to 4 meters in length. No drug could penetrate from the terminal segment through all the proglottides to reach the head and cause its death.

The treatment still consists in the administration of an anthelmintic drug by mouth after proper preparation of the patient. The patient should take a light diet for two days. A large enema of cold water or a thorough saline purge should be given. No breakfast should be taken on the day the drug is administered. The best remedy is perhaps pelletierine, which is not suitable for children and is expensive. The dose is from 0.26 to 0.5 Gm. (4 to 8 grains) with 0.3 Gm. (5 grains) of tannic acid in sweetened water. For children the oleoresin of male fern is best. Four doses of 15 minims (0.9 cc.) each in

capsules is given at intervals of an hour, followed by an active purge. The dose required can be considerably reduced by giving it through a duodenal tube, thus reducing the danger of toxic effects. Pumpkin seeds, kousso, powdered kamala, and thymol are also used.

TRAUMA AND BRAIN TUMOR

To the Editor:—A man, aged 38, rather athletic and always in perfect health, was struck by an automobile and thrown in the air, striking his shoulder and possibly his head as he landed on the street curb. He was unconscious for about half an hour. On gaining consciousness he complained of numbness in his right arm, forearm, hand and right foot. When allowed to get out of bed a few months later he had no control of his right leg. His speech became rather indistinct. Two encephalograms, one taken about a month and the other about two months after the accident revealed nothing. A diagnosis of cerebral hemorrhage with cerebral softening was made. About seven months after the accident the patient died. An autopsy disclosed a glioblastoma. Since I understand that this type of tumor is rather rapid in developing, I am wondering if it could have been caused by the trauma and resulting injuries incurred at the time of the accident. Please omit name.

M.D., Ohio.

ANSWER:—The query fails to mention many important signs that are usually present in both glioblastomas and craniocerebral injuries. These are headaches, vomiting, choked disks, defects in the visual fields, convulsions, uncinat fits and aphasias. It is easy to elicit a trifling trauma to the head in almost every case of brain tumor. Glioblastomas begin abruptly, and hemorrhages and degenerative lesions are the most common two changes found in this type of tumor. Further, this type of neoplasm is very malignant, grows rapidly and inevitably terminates fatally within twelve months. If it is certain that this man was perfectly well previous to the automobile accident, one must by exclusion state that the accident was a factor in producing this tumor. One must not forget the possibility that the man may have had a brain tumor and then had a convulsion or an attack of petit mal which made possible the automobile accident. In this way the accident may have been an aggravating factor of a preexisting lesion.

WRITERS' CRAMP OR EFFECTS OF FOREIGN BODY

To the Editor:—A man, aged 30, a surveyor and draftsman, has for the past eighteen months been having an acute cramping of the thumb, index and middle fingers of his right hand after writing a short time. He is of quite stable temperament and physically I can find nothing abnormal. His past history is negative except that about fifteen years ago a large wooden splinter entered his right forearm over the extensor muscles. The splinter was never removed and until about two years ago remained readily palpable beneath the skin. The Wassermann reaction is negative and the urine and the blood count are normal. Roentgenograms of the cervical and upper thoracic spines and of the right arm and forearm and hand give normal results. I have made a diagnosis of writers' cramp. Would you suggest any other diagnosis and any form of treatment? At present he is attempting to learn to use his left hand and I have given him a few diathermy treatments over the arm. Please omit name.

M.D., Hawaii.

ANSWER:—Under ordinary circumstances the diagnosis of writers' cramp would be correct, but in this particular case, in view of the migration of the wooden splinter to the depths of the forearm, and in the absence of any symptoms pointing to any other cause for the cramp, it must be assumed that the splinter is lodged in the substance of the extensor muscles or adjacent to the nerve supply to the extensor muscles, causing irritation of and unusual contractions in the extensors of the thumb, index and middle fingers. Soft tissue roentgenograms may be made to identify, if possible, the shadow of the splinter. Deep palpation may elicit some particular point of tenderness or a thickening of tissue that would give a clue to the location of the splinter. If either or both of these methods indicate the probable site of the splinter, it should be removed by operation.

DESTRUCTION OF SINUSES IN PENIS

To the Editor:—I have a patient with hypospadias. In addition to the hypospadias there are two sinuses, which are small and parallel the main channel for about 1 or 1½ inches. The patient has a gonorrheal urethritis. Would it be better to open the sinuses or treat them by injection? I have been injecting 5 per cent silver nucleinate into the sinuses with a blunt irrigating needle.

D. J. ZERBOLIO, M.D., Benld, Ill.

ANSWER:—The best way to clear up a condition such as discussed is by fulguration. A fine electrode can be placed in each tract, down to the bottom, and with a mild current the tract can be completely destroyed. This is much better than silver nitrate injections, which are often followed by severe reaction and at times by abscess formation.

PREVENTION OF EXCORIATION OF SKIN AFTER ILEOSTOMY

To the Editor:—What can be done to prevent and to relieve the excoriation of the skin of the abdomen by the drainage from a ileostomy? When excretion through the incision is complete, i. e., there are no bowel movements, what can be done to shunt some food through and reestablish normal function? In cases in which the ileostomy is so high that insufficient digestion and absorption have taken place to maintain body weight, what is the best procedure to follow?

DONALD W. RICHIE, M.D., Croton Falls, N. Y.

ANSWER:—Excoriation of the skin around an ileostomy may be prevented by protecting the skin by some substance that is impervious to the intestinal juices: petrolatum, zinc oxide ointment, kaolin paste. The last named is the most effective. It should be applied as a thick paste and allowed to dry before dressings are applied. Aluminum paste also has been recommended. A discussion of this by McLanahan and a formula may be found in THE JOURNAL, January 30, page 385.

When the excretion through the excision is complete, few measures short of surgery are of benefit in reestablishing the normal function. Occasionally a small catheter may be passed into the lower loop of the bowel and fluids and food administered by this means. However, in most cases it will be necessary to open the abdomen at the site of the fistula and make an anatomic closure.

In high fistulas of the small intestine the wound may be protected by continued suction and the body weight and fluids maintained by the administration of subcutaneous and intravenous saline and dextrose solutions. This type of case, however, will almost invariably require operative closure unless the fistula is a duodenal one, which more likely will respond to continued suction siphonage.

BLOOD SEDIMENTATION RATE IN SYPHILIS

To the Editor:—What effect does syphilis have on the blood sedimentation rate?

J. B. STOKES, M.D., Ottawa, Ill.

ANSWER:—The blood sedimentation rate is increased in syphilis, as in many other infectious diseases. This is especially true of the secondary stage, and of the tertiary stage when there is progression of the disease. However, the sedimentation test is of little value in the diagnosis of syphilis, as there are many causes of accelerated sedimentation of the erythrocytes. A positive Wassermann and Kahn test are diagnostic of syphilis. A patient may have syphilis with a negative Wassermann and Kahn reaction. Only 80 per cent of patients with syphilitic aortic aneurysm give a positive Wassermann test. A positive Wassermann reaction is diagnostic of syphilis; a negative reaction does not always exclude syphilis.

TREATMENT OF HYDROCELE

To the Editor:—In the answer to an inquiry concerning the treatment of hydrocele (THE JOURNAL, March 20, p. 997) it is stated that the so-called bottle-neck operation offers excellent results. I beg to differ. When it was introduced some years ago, the simplicity of the procedure appealed to me, as it did to others, very much, and I did a number of such operations. To my great regret, however, I was obliged to abandon it for the reason that several of my patients were left with persistently enlarged testes. I have seen several reports of a similar experience. I have never seen any adequate explanation offered as to why it should occur. The most satisfactory type of operation, in my opinion, is excision of the sac, cutting it away 1 or 2 cm. from the point where the sac is reflected onto the testicle. This is best done through the high incision over the external abdominal ring. The simplest type of operation, excluding injection, is to open the hydrocele through a scrotal incision and pack the cavity with gauze.

JOHN D. SINGLEY, M.D., Pittsburgh.

"GLYCOSURIA IN PNEUMONIA AND OTHER INFECTIONS"

To the Editor:—The query and answer on this subject (THE JOURNAL, January 2, p. 64) do not seem to me to be entirely justified. The gist of this answer appears to be that: 1. Infection or toxemia damages the pancreas and decreases the secretion of insulin. 2. Insulin is indicated in the treatment of such glycosurias. 3. High carbohydrate treatment causes harm by exhausting the islets of Langerhans. It would not matter so much if this answer represented merely a difference in opinion regarding the theoretical aspects of carbohydrate metabolism. I believe, however, that the therapeutic advice implied by the answer is wrong and dangerous because: 1. There is good evidence that infection or toxemia produces its effect not by decreasing the amount of available insulin but by interfering with the physiologic action of insulin whether derived from the patient's own pancreas or administered from without. 2. There is evidence that the administration of insulin to the toxic organism, except when diabetes mellitus is also present, may actually shorten life. 3. There is evidence that the administration of high carbohydrate treatment is not contraindicated but is rather the most effective method of treatment.

Director of Metabolic and Endocrine
Research, Michael Reese Hospital.

Council on Medical Education and Hospitals

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Thirty-Third Annual Meeting, held in Chicago,
Feb. 15 and 16, 1937

(Concluded from page 1366)

DR. CHARLES E. HUMISTON, Chicago, in the Chair

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 16—AFTERNOON

Medicine in Education

MAX MASON, PH.D., Pasadena, Calif.: Medicine is one of the most interesting of pursuits, not only for its enormous importance but also for the progress it has shown, which is characteristic of our whole procedure, the procedure of the rational animal. We start doing things by rule of thumb, intuition, and accomplish them through a thing called an art. As the art grows curiosity grows, and the art of healing became analyzed into a set of component sciences. As the needs of the human being for betterment became greater, the analyzation into sciences gave an increasing knowledge so that we kept naturally with growing needs and growing knowledge and a continual extension of the domain over life that the practicing physician had to exercise.

We are not going to force on the medical profession a fundamental rôle in education. It is going to force itself on the medical profession. A profession that has to do with the physical and mental well being of the race cannot neglect the most important factor in that physical and mental well being, which is education. Education is primarily an inculcation of the idea of rational procedure, procedure based on accurate scientific knowledge, and the practice of medicine was a pioneer in that function. Mental attitudes are as contagious as measles and, by example, the medical profession has been educating in rationality of living. We have had 300 years of intense application of the method of science since the new learning, only 300 years, but it has been an immense period. It has been a period of freedom from fear, release from appeal to authority and superstition, and the gaining of an immense amount of detailed, accurate knowledge about the forces of the universe. Basic sciences have grown, have become one—physics, chemistry, mathematics. With a rapidly increasing theoretical knowledge of the sciences has come a rapid increase in the technological applications of them, so much so that it is a commonplace to say that man, having mastered his physical environment, has now created for himself powers over the forces of nature so great that they threaten his own destruction.

The pessimist insists that it is true, and would declare a moratorium on scientific research. "We already know too much science" is the word. Man knows more about the forces of nature than he should. He is going to use them and he is using them for destructive purposes. We see economic selfishness, racial passion and prejudice determining these things and in the growth of large political groups with the enormous power for destruction that they possess, with the hatreds, passions and prejudices engendered by narrowness of mind, the pessimist finds the danger of the race, and many go so far as to say "Stop your theoretical considerations. You are not going to have any universe left to carry on your great experimentations."

What is the cure for it? We have said that education is the cure for everything, and perhaps it is. At any rate, professional educators are stirred up over the fact that they are not meeting the fundamental needs of the circumstances and there is a great deal of discussion along the theme of education in a changing world, the university in the new world. If these discussions result in the deepening of insight into the educational process and the ceasing of the teaching of dead ideas and pseudoculture, it will be all to the good. But if they mean throwing overboard basic, sensible, disciplinary pro-

cedures and having every student in the university become a young Demosthenes and a solver of all the social problems of the world, if they mean that he shall be taught of the exact circumstances surrounding our economic and political life so he can step out into citizenship and solve the problems of the world, then I do not think we have much to hope for. We need education for a world of change; the student should be taught to participate in any situation and he need not be taught the details of the situation. We have the same simplicity today for mental training that we have had all the time. We have to find the highest common factors of successful living. It is more important than all of the informational knowledge and training in technic that you could give. There is a technic of rational living and the medical man has been teaching it through his practice for all these generations. It is the objective application to problems of individual and group living of the scientific method.

What is the matter with education? I suppose a million people have given speeches about it and every man differs. Education is a peculiar process, anyway. It is an artificial process, in the first place. The natural form of education is experience, but we haven't time to put ourselves through experience. We try to give them epitomized experience. We try to give them the benefits of it without their having had it, and that is a pretty difficult thing. We used to have educational procedures of great value simply existing in our pioneer life. There, one was in touch with reality day after day. With increased artificiality of living, the checks on method of conduct have become less and education has begun rapidly to overshoot the mark, to deal with detail and with information. Students of education and teachers are beginning to realize and beginning with the primary grades they are beginning to understand that man is a personality that can be enormously influenced by his experience, and it is their duty to influence him so that every person shall have the great opportunity of being born into a world where his personality can be formed by educational procedure into one of the highest intellectuality and the greatest emotional stability that his inherited characteristics will admit of. We are far from that stage at the present time.

The medical man has been a great demonstrator of the application of objective thinking and the scientific method to the problems of life. By virtue of his intimate relationships he has had to come to grips with all the stresses that exist in the mental life of people. He has had to broaden out in his sympathies and in his understanding. He is an example of the rational animal and he can't forget it and it is more important than the cures he gives for the sore throats or for anything else. Whether he wants to be or not, in this simple manner, he has been a profound and enormous force for informal education to the end and aim of teaching the technic of living that is right and that is proper.

There is another slant on this need of education. It consists in the familiar picture of our civilized world today with regard to mental disorder. Is it any wonder that man is showing the casualties of his evolutionary struggle? If we start with the simple unicellular organisms, I don't suppose amoebas are subject to inferiority complexes or compulsion neuroses. They are simple. Man enjoys his preeminence because of the development of a highly specialized central nervous system geared to his whole physiologic make-up, but the meanings of that physiologic gearing have been lost. After coming through in the process of adaptation to his environment with a set of accelerators of action in his hormones, with the gearing of emotion, thought and action correspondent to the necessities of uncivilized life, he suddenly bursts out and becomes an artificial liver. He lives in pseudo-experience more than he does in real experience. His thoughts are the ghosts of experiences and you can't go through an intellectual process without arousing a high degree of emotional picture behind it, because every intellectual process calls into being a residue of all the memories of the life of the man and those memories are colored highly with emotional content.

He sits, doing desk work, thinking of things, worrying about things, pictures flashing through his mind consciously and subconsciously, dramatic pictures involving responses of anger,

of pain, of worry, of happiness, of whatnot. The emotional response is present in the artificial life of the mind to as high a degree as in the real life of the savage when he meets a physical danger, but he doesn't burn it up. He goes on poisoning himself with it. He lives in harmonic imbalance month in and month out, an abnormal, strange, new thing, this life of the mind and of the emotion, new from the evolutionary point of view. Is it any wonder he suffers from disorders? No.

What is the answer? To understand the process and to aid in keeping man sane and balanced as he proceeds evolving his own civilization. The thing is with us so much that we fail to realize its dramatic and terrible importance no matter how many speeches are made of it and how many reports are made of it.

If there is any major truth, it is that the profound program of human beings today in the advance and application of knowledge lies in a deeper understanding of the causes of mental disorder, of the methods of mental training, emotional and intellectual, to the end that we shall bring out from the race as stable, as intelligent and as happy a group as is possible, and we are far from that at the present time, far not only because of lack of knowledge but far because we are not applying the knowledge that we should apply. We have at best a condition of rationality, and if we took the index of rationality of all the human beings and plotted them we would have a broad curve, spread out, and if we took the spectrum of any individual we would have a thing that looked like the solar system, with heights and deep grooves. Any of us who have just passed through a political campaign will recognize that fact. The ability to maintain an emotional stability, a normal degree of lack of idiotic credulity, a reasonable degree of speaking decently of a man who probably is decent, and the ordinary modes of conduct of a rational human being are lost in about 70 per cent of men whom one would call educated. They are incapable of rational thought on that subject. We may have lost something of our conceit in thinking of man, but we have gained enormously because we have put him into the heart of nature. We are thinking of him as a heart of a universe apart and composed of parts subject to study, subject to training and, above all, subject to regularities of behavior that can be understood. Is there going to be knowledge adequate to that, the great problem of humanity? I am enthusiastic about the trend of sciences to a degree that I admit is completely irrational. At that point my curve of rationality disappears. I see in these few decades the turning point in the history of the world as regards the use of science. Three hundred years has evolved beautiful methods and an enormous array of facts and they have been used for almost nothing of any importance, but at last we are getting somewhere.

The tools of the laboratory, the methods of science are being turned with enormous rapidity on the one problem worth while, self understanding of the human being, his characteristics, his action patterns, the somatic and the psychologic factors determining his action as a normal human being. At last there is a reason for turning on all this knowledge, more than for the refrigerator, the radio, more than for any of the labor-saving devices, more fraught with potentiality for human welfare.

All the sciences are at last combining in one attack that is worth while, the attack on an understanding of man, and you representatives of a great profession can see what is coming, for you are the applicators of that science. You are the cutting edge, and the medical profession will be the cutting edge of that tool which is composed of all human knowledge, the cutting edge in applying to the benefit of human character and human happiness this dearly won knowledge of the physical and chemical behavior of man. I think it is a picture of the most sublime optimism. I think it literally is a turning point in the history of a race. Consciously or unconsciously, 300 years of the scientific method has led to the point at which this knowledge can be put to something worth while. You have been forced to be psychiatrists, psychologists, anatomists. The beauty of all science is that it seems to grow more and more complex and then sweeping generalities arise that make a vast array of fields understandable and comprehensible where before it seemed incredibly difficult, and I believe that will be

the same thing in this enormously complicated field of the psychobiologic nature of man.

Simplicities are arising. Broad and deep channels of understanding are being created into this realm of difficulty and when we get through, what is education going to mean a decade after decade knowledge of what we are educating comes? Think of education in the past. In whose hands was it? Was it in the hands of people who knew anything about growth and development? No. The medical profession in the past was a great rationalizer in giving an example of unselfish, sympathetic application of scientific knowledge. It taught by example the rational approach instead of the passionate, irrational approach to the problems of life. Education is overshooting the mark in its own province by forty years, and one finds today that the best reading for an adult is a high school textbook. In a higher degree, we are training distorted minds and warped emotional bases for performance. Let's stop. Let's train the mind and the emotional background so that if they perform or not they will be able to perform well.

DISCUSSION

DR. LOUIS B. WILSON, Rochester, Minn.: The American Board of Ophthalmology was developed twenty-three years ago. Ten years ago the National Board of Medical Examiners was approached by several specialty groups with reference to their taking over the job of the certification of specialists. At that time a committee was appointed consisting of the three surgeons generals of the federal services, the secretary of the national board and myself, to consider the question of the certification of specialists. It took us about five or six years before we could get the groups concerned together. Yet out of chaos has come a certain amount of order and now the American Medical Association, quite properly, is thoroughly behind the proposition. Hitherto, all of our examinations and all of our work has been directed toward whether we should or should not turn out students as certified physicians to practice medicine in the community. We have given little thought to their future specialism; in fact, we have carefully avoided that. Now the medical profession as a group realizes that it is necessary to take some cognizance of the possibilities of their becoming specialists. Every dean here who has concerned himself in the last few years with the selection of men for departments in his medical school knows that it is practically impossible to get reliable information in adequate amounts concerning the individual whom he is considering for the heading of a department in his medical school. If we can devise, right now, in connection with our graduate work, some adequate record of an individual's attainments on his way up through the medical school, because it isn't there now, through the graduate school, because it isn't there now, until we come to select men for the faculties we are not only going to have better general practitioners and better specialists in all fields but we are going to have better men on our faculties in our medical schools. The present method of listing the names of men who say they are confining their practice to this or that, as now made in the American Medical Directory is inadequate. The present method of stating the residencies in hospitals that are approved for training in the specialties is based on inadequate and inaccurate data, but we all agree that it must be reformed. But in the reforming of that let there be certain ideals. Those I have mentioned of recording a man's attainments, his abilities, his skill—those are to me most significant.

DR. GEORGE H. MEEKER, Philadelphia: It seems to me that we start off on the wrong foot to speak of medical specialization when what we mean is clinical specialization. The whole atmosphere of this movement is clinical specialization. In order to get clearly in our mind what is meant by a specialist we have first to think of the patient, not of the physician who claims himself to be a clinical specialist or of the instrumentalities whereby he becomes so certified. We ought to start by the dictum that the patient is entitled to that sort of a clinical service which modern medical knowledge and skill is potentially capable of rendering. If we start with that thought in mind it makes it easier to understand what we should mean by the clinical specialist. In one way he could be called a

master clinician, but the simplest way is to think of him as a clinical expert. Since only the expert may render to the patient that clinical service which is the patient's right, it is proper that there should be means not only for training physicians as clinical experts but also that there should be certifying boards such as we have talked about today duly authorized to make known to both patient and the profession who are those physicians who have become so designated. To my mind the general practitioner is the most important of all clinical specialists. If he is real, I argue that he should be a certificant of the American Board of Internal Medicine, just as fully qualified in internal medicine as any professing internist, and in addition he should be an expert in the case management of his patient. When we approach the details of the activities of the various boards, we should be very precise in our terminology. If we look at it from the standpoint of instrumentalities, I think we would be much more precise if we would speak of it as graduate clinical education rather than as graduate medical education. One of those instrumentalities has been special hospital residencies. If all we are going to do is to call special hospital residencies the instrumentality alone for doing this work, let us say so. Let us not leave it so vague as it is in the statement of the general principles of the advisory board for the medical specialist. For instance, we start off by saying "intensive graduate training." If we mean by intensive graduate training what a good residency and a specialty imply, let us say so. Otherwise, the wording is misleading. In other words, I haven't the slightest idea of what the word "intensive" here means. Probably the board has a clear idea of what that means, but I should have rubbed that word out entirely if I had my say. I have tried to emphasize that it is important to have our terminology correct. I don't think the terminology is right and I don't think our thoughts are clear on certain vital points.

DR. B. R. SHURLY, Detroit: If we are to progress, it is essential that the medical school, the hospital, the American Medical Association, the Association of Medical Colleges, the deans and all the organizing forces of education should be brought together on a perfect understanding of what is the best thing to do at this time in order to give young men the best we have and to let them know earlier what their training for specialism may be. With twelve special boards, young men are at sea as to what the requirements of those boards may be. There is a terrific amount of confusion. We have mapped out a premedical education for our students in medical colleges. It is just as necessary to have an earlier prespecialty education, to have the graduate schools carefully outline their ability to take care of these men. The Board of Otolaryngology has examined more than 2,000 men for certification. The progress has been great. The men who come up at present are much better prepared. We have a necessary 160 new men each year required in a specialty to cover the demands as they are in this country. At present there are only 100 hospital residencies, and only fifty that are of a high order. With this rapid advance in specialism, the progress is not perfectly even in the education of these men. Some of them are woefully deficient in the proper essentials of bedside medicine and general medicine. Under our progressive methods of carrying education into higher and higher fields we should not forget that general medicine cannot be; as far as the eye, ear, nose and throat is concerned, absolutely cut off at the neck, and that is the general trend at present. My plea is that, in the educational development of this new era, we rest firmly on the foundations of medicine and surgery as our rock of Gibraltar by which we steer medical education for specialists into the future.

DR. CHARLES GORDON HEYD, New York: I agree thoroughly with the preceding speakers. The educational value of research is of course apparent to every educator, but the problem of research shall not be weighed indeterminately in the examination of the qualifications for the specialist. Precision of terms we all welcome, and the fact that all specialism must fit into the general pattern of medical education I think we are agreed on. I want at this time, and I did not intend to slight three

organizations, to bring the laurel of grateful remembrance to the Board of Ophthalmology, which is a pioneer; to the Board of Otolaryngology, and to the Board of Obstetrics and Gynecology, which has entered the field more recently.

Relation of the American Medical Association to the Certification of Specialists

DR. CHARLES GORDON HEYD, New York: This article was published in full in *THE JOURNAL*, March 27, page 1017.

The Increase in the Number of Practitioners in the Country

DR. HAROLD RYPINS, Albany, N. Y.: An accurate count of the number of physicians actually engaged in the active practice of their profession in any given jurisdiction is surprisingly difficult to obtain. The 1936 edition of the American Medical Directory gives comparative figures for the number of physicians in this country by states and totals for the country for various years between 1906 and 1934. These figures would appear to be highly accurate. However, the same directory lists 24,013 physicians in New York State, whereas the records of the New York State Department of Education show that only 21,020 were registered as in active practice. Accordingly, there is a difference of 2,993, or 14.2 per cent, between the number of physicians merely residing in New York State and the number sufficiently active in the practice of medicine to pay a two dollar registration fee legalizing such practice. This would indicate that the usual number of physicians given for any area is about 15 per cent too high, if our object is to count only those physicians actively engaged in the practice of their profession. This disproportionate increase in the number of physicians in New York during the past decade led me to study the cause of the increase for the country as a whole. In making this study I have used New York State data, as they are most easily available, but I have attempted to correlate them with information derived from a questionnaire sent to all state licensing boards, to which thirty-six complete replies were received.

The annual increment in the number of physicians licensed comes from four sources: (1) recent graduates of registered medical schools throughout the United States and Canada, (2) American students graduating from foreign medical schools, (3) physicians licensed in other states or countries obtaining licenses under reciprocity agreements or by endorsement, and (4) native graduates of acceptable foreign schools.

The figures for the number of first year students admitted to medical schools throughout the United States since 1933, when the peak was reached, indicate a falling off of 7 per cent in the number of freshmen admitted this year and a diminution of 12.5 per cent in the number of students admitted during the past four years. This is largely the result of the inspection of medical schools by the Council on Medical Education and Hospitals of the American Medical Association, in conjunction with the Federation of State Medical Boards of the United States and the Association of American Medical Colleges, and is due to the finding that a number of medical schools were accepting a larger number of students each year than their laboratory and clinical facilities warranted for the maintenance of proper educational standards. The number of freshmen admitted into the nine registered medical schools in New York State has dropped from 716 in 1934-1935 to 685 in 1935-1936, or a fall of 4.7 per cent in one year. In short, there is a constant decrease in the number of new graduates of registered medical schools; that is, in the most eligible and desirable group of applicants for licensure.

The number of American students studying abroad reached the high point of 2,054 in 1932-1933. This number fell off slightly during the succeeding two years but has dropped sharply to 1,494 for the year 1935-1936. The falling off in the number of American students studying medicine abroad is the result of the activities of the Joint Committee on Foreign Medical Students, composed of the American Medical Association, the National Board of Medical Examiners, the Association of American Medical Colleges and the Federation of

State Medical Boards. As a result of this committee's activities there are at present only two countries, namely, Italy and the British Isles, in which American students may pursue their professional studies in the expectation of obtaining admission to licensure in most of the states.

In the year 1935, 172 graduates of New York medical schools, licensed in New York State, obtained licenses in other states under reciprocity agreements or by endorsement of their New York licenses. In the same year, 175 licenses of other American states were licensed in New York under similar circumstances. It is evident that the inflow and outgo of physicians from other states by endorsement or reciprocity practically cancel out, and it is eminently desirable that qualified practitioners in one state should be able to move with as little difficulty as possible to another. The influx of physicians from other states is not a factor in the increased number of physicians during the past decade.

The table gives the number and percentage of foreign physicians licensed in thirty-six states for the past year and for the past five years, respectively, as compared with New York State. It appears that during the past year the medical population of thirty-six other states was increased 0.1 per cent by the licensure of foreign-born physicians, while the medical population of New York State was increased 1.4 per cent, or fourteen times as much as the country at large. Similarly, for the past five years the increase in the other states was less than 0.4 per cent, as compared to 4 per cent in New York State. Thus, the licensure of foreign-born physicians in New

of a foreigner's obtaining admission to advanced standing in recognized American medical schools, this ruling, again, is almost prohibitory.

Of the thirty-seven states for which data were available, twenty-one practically never admit foreigners to examination. This leaves sixteen states where licensure is a possibility. In all these sixteen states, however, it is now necessary for the applicant, no matter how many years he has been out of medical school, to pass the full written licensing examination required of recent American graduates, in a language which is foreign to him. When it is noted (1) that the average foreign applicant has been out of school from ten to twenty years, (2) that it is extremely difficult even for Americans to pass a state licensing examination five years after graduation and (3) that it is profoundly difficult for students over 30 years of age to learn to speak and write adequately a foreign language as difficult as English, it is evident that the requirement of passing the regular medical licensing examination in the English language is an obstacle that will discourage and stop all but most highly intelligent and persistent applicants.

Bearing in mind that licensure by endorsement without examination has not been permitted even in New York State since Oct. 15, 1936, we may subtract the 482 foreigners so licensed from 1,439, the total number of foreign graduates licensed in thirty-seven states during the past five years. This leaves only 957 foreigners who have been able to pass the medical licensing examinations in the various states, or an average of less than 200 foreign-born graduates a year for the entire country.

Graduate Instruction and the State Medical Association

DR. CHARLES R. SCOTT, Twin Falls, Idaho: The undergraduate phase of medical education has reached an excellence in the United States that may well afford comfort and assurance to the nation. Immediate graduate instruction has also attained a high degree of excellence in the hands of universities and allied hospitals, with their fellowships and foundations for research. But there is a further field for graduate instruction to those men who practice remedial and preventive medicine all over the nation in town and hamlet and who have been weaned from their alma mater ten and twenty and thirty or more years. These are the men on whom a majority of the people must depend for health. And these are the men who are not permitted for geographic and economic reasons to return to the medical centers to partake of the organized instruction there prepared for them. Medical educators have known this need and have attempted to meet it. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, June 30, 1934, published a report by Dr. Leroy E. Parkins of Harvard Medical School which shows the conscientious efforts being made, as have the news items in THE JOURNAL since that date. It seems evident that many of these generous efforts have not been entirely satisfactory to either the donors or the recipients. There has seemed to be a sense of their futility to either essayists or their audience. The inevitable result of such feeling is poor attendance. At the time I assumed the responsibilities of leading our Idaho state society I had finished a term as member of the House of Delegates of the American Medical Association and was quite sensitive to the need for an effective organization of medical men for protective purposes.

In an effort to establish a satisfactory state medical society meeting, we in Idaho evolved a plan which has been found satisfactory. We devote five days to our meeting. This gives time for the teachers to get their lessons into our minds in a good pedagogic manner. We organize a course of instruction on topics of value to the most doctors and to the most patients possible. The members from all over the state are free in suggesting to us the topics on which they feel they need to be brought up to date. We have one instructor in a fundamental science who lays the foundation for the clinical subjects to be treated each day. We have had a physiologist, an anatomist and a pharmacologist, and this year we shall have a pathologist. We obtain five active teachers of the type whom the students consider to be the men from whom they really learn the most. These will be found to be men who know their subjects well and who are gifted pedagogically. The men are chosen

Licensure of Foreign Physicians

	Number of Physicians	Foreign Physicians		Foreign Physicians	
		Licensed 1935-36	Per Cent Increase	Licensed 1931-36	Per Cent Increase
New York.....	24,013	343	1.4%	961	4.0%
Thirty-six other states	115,412	114	0.1%	478	0.4%

York State during the past five years is ten times as great as their licensure in thirty-six other states for which data are available. Of the 961 foreign physicians licensed in New York during the past five years, 479 were licensed after examination. Four hundred and eighty-two were licensed without examination, by endorsement of their licenses, on submission of satisfactory evidence of acceptable education and not less than five years of legal and reputable practice. All the 482 physicians licensed without examination by endorsement are foreign born and include Canadians. A recent ruling in New York requires all foreign-trained applicants for any profession to pass the full written licensing examination for admission to the profession.

It is clear that the licensure of foreign physicians is the largest potential source of increase in the number of practitioners in a community. It is of interest to note the various devices which different states employ to restrict licensure of this group. These measures include (1) full American citizenship requirement, (2) regraduation from an American medical school, (3) internship in recognized hospitals, (4) period of residence in the state, (5) passing of a regular written licensing examination in the English language and (6) combinations of these. Of the thirty-seven states, including New York, for which data are available, nine have no citizenship requirement, sixteen require first papers only and twelve require full citizenship for licensure. Thus a residence of at least six years is required for licensure of a foreigner in Arkansas, Delaware, Florida, Georgia, Kansas, Kentucky, Michigan, Minnesota, Nebraska, South Dakota, Tennessee and Utah. Except in the case of a young man with private means this regulation is practically prohibitory. The following ten states require a foreigner to obtain an additional medical degree from an acceptable medical school: Delaware, District of Columbia, Kansas, Kentucky, Louisiana, Michigan, Mississippi, Nevada, New Mexico and Tennessee. In view of the extreme difficulty

after a conference first with their dean and then with them in person. We always obtain these men from the faculty of one medical school. They then organize themselves into a sort of traveling faculty and choose one of their number as its dean. Through him the topics are organized and correlated. The men whom we have had have told me that they have found it necessary to hold numerous conferences to get their symposiums harmonized. We have five fifty minute lectures each day, three in the morning and two in the afternoon. At noon there are round table luncheon discussions, one for each lecturer, and these are considered most profitable. We find that, at our average age, five hours is about all we can take with profit in one day. All of the expenses of our faculty from home town back to home town are paid by our society, and personal salesmanship is tabu. It is probably better to have the faculty from so far away that this temptation is removed. We devote one evening to a public meeting addressed by some of our faculty. The people appreciate and approve this feature. We devote another evening to a banquet, to which we invite as our guests a considerable number of influential laymen from all over the state. This banqueting assembly is addressed by a fluent and prominent man, not of our profession, on a topic not related to medicine. By having these lay lectures and the banquet address we are able to accomplish statewide newspaper publicity covering the nature of our meeting and the opportunity offered the doctors of the state that brands the doctor who never attends with the people in his community. During the five days there are ample hours for the business of the state society to be carried on without interfering with any man attending the lectures. There is also ample time for golf and other diversions.

This experiment of ours was authorized after several years of tentative suggestions to our house of delegates and was launched with some-trepidation by its proponents. The results have been: 1. An increase in our attendance from around fifty up to around 175. There are not 300 doctors in active practice in the state. 2. An increase approaching 50 per cent in active members of our society and an enthusiastic appreciation from the rank and file of the profession in the state as to the value of the society and its meeting. 3. The establishment of a foundation fund, now approaching \$10,000, the income from which is to be used only for the expenses of graduate medical education under the auspices of our society. 4. An increased respect for our profession in our state together with an added weight of influence by the profession on the legislature and the state administration. 5. The enthusiastic cooperation from the university faculties who have served us, together with encouragement from them to make this report and to continue and perfect our plan.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examination of state and territorial boards were published in THE JOURNAL, April 17, page 1367.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Oral examinations for Group A and B applicants will be held in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Practical examination will be given at Philadelphia in June. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Practical, oral and clinical examinations for Group A and B applicants will be held at Atlantic City, N. J., June 7-8. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 7 and Chicago, Oct. 9. All applications and case reports, in duplicate, must be filed at least sixty days before the date of examination. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Atlantic City, N. J., June 8. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Philadelphia, June 2. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., June 4-6. Sec., Dr. Byrl R. Kirklín, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF UROLOGY: Oral examination. Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Virginia December Examination

Dr. J. W. Preston, secretary, Board of Medical Examiners of Virginia, reports the written examination held in Richmond, Dec. 9-12, 1936. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Howard University College of Medicine.....	(1935)	81,	81
University of Virginia Department of Medicine.....	(1934)		86

Twenty-seven physicians were licensed by reciprocity and 4 physicians were licensed by endorsement from July 31 through December 10. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Yale University School of Medicine.....	(1930)		Mass.
George Washington University School of Medicine.....	(1907)		D. C.,
(1920) Maryland			
Georgetown University School of Medicine.....	(1932)		Maryland
University of Illinois College of Medicine.....	(1913)		Iowa
State University of Iowa College of Medicine.....	(1902)		Iowa
University of Louisville School of Medicine.....	(1929)		Kentucky
Johns Hopkins Univ. School of Medicine.....	(1930, 2), (1932)		Maryland
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1914), (1928)		Maryland
Washington University School of Medicine.....	(1905), (1932), (1934) Missouri		
University of Nebraska College of Medicine.....	(1919)		Nebraska
Ohio State University College of Medicine.....	(1928)		Ohio
University of Oklahoma School of Medicine.....	(1935)		Oklahoma
University of Pennsylvania School of Medicine.....	(1928)		Penna.
University of Pittsburgh School of Medicine.....	(1932)		Penna.
Medical College of the State of South Carolina.....	(1923)		Ohio
Meharry Medical College.....	(1935)		Tennessee
University of Tennessee College of Medicine.....	(1929), (1932)		Tennessee
Medical College of Virginia.....	(1926)		W. Virginia
University of Virginia Department of Medicine.....	(1928)		New York,
(1935) Tennessee			

School	LICENSED BY ENDORSEMENT	Year Endorsement of
George Washington University School of Medicine....	(1917)	U. S. Navy
Georgetown University School of Medicine.....	(1935)	N. B. M. Ex.
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1932)	N. B. M. Ex.
University of Virginia Department of Medicine.....	(1932)	N. B. M. Ex.

New Mexico October Examination

Dr. Le Grand Ward, secretary, New Mexico State Board of Medical Examiners, reports the written examination held in Santa Fe, Oct. 12, 1936. The examination covered 11 subjects and included 75 questions. An average of 70 per cent was required to pass. Two candidates were examined, both of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
School of Medicine of the Division of the Biological Sciences	(1935)		86.1
Kansas City University of Physicians and Surgeons, Missouri	(1929)		77.9

Twenty-five physicians were licensed by endorsement from October 14 through December 20. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement of
University of Arkansas School of Medicine.....	(1927)	Arkansas,
(1932) Louisiana, N. B. M. Ex.		
College of Medical Evangelists.....	(1936)	N. B. M. Ex.
Northwestern University Medical School.....	(1933)	Iowa
University of Louisville School of Medicine.....	(1932)	Kentucky
Tulane University of Louisiana School of Medicine.....	(1928)	Louisiana

Book Notices

Diseases of the Coronary Arteries and Cardiac Pain. Edited by Robert L. Levy, M.D., Professor of Clinical Medicine, College of Physicians and Surgeons, Columbia University, New York City. Cloth. Price, \$6. Pp. 445, with 97 illustrations. New York: Macmillan Company, 1936.

This is in reality a series of short reviews by noted American authorities on various aspects of this important medical problem. As the editor explains, the various chapters are wholly the views of the individual contributors, and consequently it is not surprising to find conflicting opinions expressed. This book is after all a survey of the present status of a field that is still new and constantly changing. Nevertheless, the careful student will find the book of inestimable value, since the survey of each particular phase is by a recognized authority in the field. That these reviews are admittedly biased when dealing with the borderlines of knowledge is a favorable rather than an unfavorable aspect of the book. Knowledge cannot be dissociated from personalities, and it is much more illuminating to know the point of view of an authority actively at work in a field than a more noncommittal essay by a reviewer of literature. In addition to the specialist, the medical student, the general practitioner and the internist will find themselves well repaid in reading the simple authoritative presentations of the so-called more practical sections of the book, although they may soon get lost in the intricacies of the technical arguments of certain of the "less practical" sections.

The introduction is written by A. E. Cohn in his usual delightful philosophic tone. The historical note written by J. B. Herrick presents the development of the subject and the American contributions clearly and with much too much modesty in regard to the historical importance of his own pioneer contributions in 1912 and later. J. T. Wearn, while perhaps unduly stressing direct communications between coronary arteries and heart cavities, gives a fair assay of the anatomy of the coronary system. C. J. Wiggers gives a detailed and intricate presentation of the physiology of the coronary circulation. It is a good summary of the recent work of his laboratory interpolated in the light of work done by other investigators. A simpler presentation or at least a summary would have enhanced this excellent chapter. The chapter on pharmacology by F. M. Smith gives a straightforward account of present knowledge. W. C. von Glahn, in comparison with other chapters, has dealt much too elementarily with the subject of the pathology of the coronary vessels. J. C. White's chapter on the pathways followed in the nerve plexuses by the pain fibers is excellent, and the physiology of cardiac pain written by C. J. Wiggers is a gem of original coordinated reviewing and description that will repay careful scrutiny. L. I. Dublin, in his chapter, has clearly pointed out the way in which statistics can be usefully applied to advance knowledge of disease. R. L. Levy in the next two chapters gives a straightforward clinical description of coronary diseases of the arteriosclerotic and syphilitic varieties. W. J. Kerr devotes a lengthy chapter of the more uncommon disturbances of the coronary arteries; particularly excellent is his summary of the history of periarthritis nodosa. P. D. White has presented an excellent clinical essay on cardiac pain, showing that the art of pure clinical description is not yet lost. The chapter on electrocardiography by F. N. Wilson is well presented and beautifully illustrated and, while biased in certain directions, merits careful perusal. The medical management of coronary diseases is dealt with as a practical problem by R. L. Levy in a brief, clear and authoritative fashion in two chapters. J. C. White presents the status of surgical methods for the relief of pain and stresses the value of paravertebral alcohol injection. The more recent surgical procedures still in their experimental stage are presented in the last two chapters by their proponents, H. L. Blumgart on complete thyroidectomy and C. S. Beck on the development of a new blood supply to the heart. Both these authors are cautious to point out that their procedures demand considerable further trial before they can be accepted as established methods of treatment.

This monograph of an advance in medical knowledge, primarily American in its source and development, is a meritorious undertaking, permitting the reader to obtain an inventory of what the advances actually have been.

Die Prophylaxe der Schlafstörung. Von Dr. med. habil. Paul Vogler, Dozent an der Universität Berlin. Boards. Price, 5.80 marks. Pp. 139. Leipzig: Georg Thieme, 1937.

The author tells us that he is not going to add another to the already great number of experimental studies on the problems of sleep. He would cultivate but a sector of this assemblage, and that relates itself to the clinical and prophylactic aspects of the situation, hydrotherapy being especially accented. In order however to afford a foundation, he reviews some of the underlying studies, thus offering a rapid summary of a few of the leading hypotheses and theories, chiefly of the physiologic schools. Thus there are brief references to the work of Hess, of Pavlov, of von Economo and of a few others of less significance. Almost apologetically, Freud's conceptions are given in smaller type, and at the end of four pages the astonishing statement is made that the freudian contributions offer no extensive study of sleep as a psychologic problem (p. 28). As only Freud's 1930 "Lectures" are quoted even in the bibliography, and Hoche's totally inadequate handling of the dream problem is frequently referred to, this show of ignorance is quite understandable on this, if not on deeper, grounds.

Dr. Vogler would posit four "fundamental" sleep factors. They are quite banal. They are sleep fatigue, the sleeping room, beds, and habits of sleep. To these sections on food supply are added light and air, equally quite superficial factors. The falling asleep, length of sleep, periodicity, and the sleep of childhood are briefly discussed and a short and inadequate note is presented on sleep walking and on the hallucinatory stages of the beginnings of sleep, also quite superficial. Thus, with reference to the latter, no mention is made in the text or the bibliography of Silberer's careful study of these hypnagogic phenomena.

Some trivial case histories are next reported and the text moves on to therapy. Goldscheider's dictum that hypnotics should be prescribed only when psychologic, physical and dietetic methods are not applicable is quoted with partial approval and emendation. Analgesic hypnotics are desirable in the presence of pain. There are three pages devoted to psychotherapy so general as to mean nothing. The final pages deal with various hydrotherapeutic procedures, chiefly the "pack," with a page or two on the continuous bath. A bibliography almost entirely of German writers closes this small brochure, which, though it has its spots of good grazing, is rather sparse feeding at best.

The Problem of Anxiety. By Sigmund Freud. Translated from the German by Henry Alden Bunker, M.D. Cloth. Price, \$2. Pp. 163. Albany: Psychoanalytic Quarterly Press, New York: W. W. Norton & Company, Inc., 1936.

This is an English translation of Professor Freud's "Hemmung, Symptom und Angst" written about ten years ago. It is one of the most important of Freud's recent contributions to psychology and is a corner-stone to contemporary psychoanalysis. Critics and commentators outside the field of analysis have for the most part been ignorant of the recent work of Freud and have praised or attacked psychoanalysis on the basis of his early work. Now there can be no excuse for overlooking the modern trends in analysis. The translator has kept to Freud's style of writing to a large degree.

Freud begins his book by differentiating inhibition from symptom. Inhibition is related to function but is not necessarily pathologic. It may be a symptom, but symptoms are always pathologic. Inhibitions are renunciations of functions that would give rise to anxiety if they were begun, as in hysteria. Inhibitions are functional limitations of the ego in order that there may be no indulgence in symbolic gratification of the repressed, thus avoiding conflict with the id, or in order to renounce gratification because of self punishment, thus avoiding conflict with the super ego.

Symptoms are substitute gratifications of what has been repressed by the ego at the command of the super ego. The ego is ordinarily quite powerless, but it does control the development of ideas and emotions into consciousness. In struggles of repression it can give a signal of distress. It can withdraw a charge from the preconscious representation of instinctive impulses and utilize such charges to produce "unpleasure" in the form of anxiety. Thus the ego is the real source of anxiety. The super ego is not the source of anxiety, since anxiety may occur before the super ego development when the

attempt to bind excessively powerful stimuli fails as a safety device. The appearance of anxiety in primal repression means that it is a biologic reaction conditioned on the first prototype of the physical manifestations of anxiety; i. e., those symptoms of dyspnea, tachycardia, and the like, appearing at the birth trauma.

Anxiety is something felt of an unpleasant character; it is accompanied by an efferent discharge in the vegetative sphere. It is these efferent discharges which reproduce the birth trauma. Birth is a physical danger with the psychologic component of basic or primal anxiety at separation from the mother. Anxiety then becomes an automatic phenomenon and a safety signal of psychic helplessness. Object loss is the precondition of anxiety. Danger of castration is danger of forever preventing reunion with the mother and identical with a second separation from her. Fear of castration at the hands of the rival father is internalized to fear of the super ego and dread of conscience or social anxiety. Thus the ego is the real source of anxiety. One must not restrict anxiety to castration fear but anxiety appears with danger of psychic helplessness in immaturity, with danger of loss of loved object in early childhood, castration fear in the phallic phase, and dread of the super ego in the latent period. In hysteria there is fear of loss of love, threat of castration in phobias and dread of the super ego in the compulsions.

Symptoms develop in order to avoid anxiety or, better said, anxiety causes symptom formation. The ego protects itself from outer danger by modifying the instinctual forces permanently because infantile objects of anxiety persist throughout life. There is a permanent reaction to danger. In the final analysis, according to present knowledge, the specific principles underlying the development of neurotic symptoms are three in number: 1. Biologic helplessness and dependence of the human infant thrust unfinished into a dangerous environment necessitating protection, care and great love. 2. Phylogenetic early demands of sexuality on the child with abrupt appearance of a latent period at the age of 5. The early demands on the child and his inability to compete have the same effect on his ego as premature contact with the world at his birth. 3. Psychologic lack of adequate differentiation of ego from id within the psychic apparatus. The dangers of reality force the ego to treat its instinctual impulses as dangers. In combating the id which is intimately connected with the ego, the ego must put restrictions or inhibitions before itself, tolerate symptoms and suffer neurotically.

This bare sketch of Freud's work does not do justice to his masterful work. The book should be thoroughly studied in order to grasp Freud's insight into human psychology and for the purpose of really understanding an important part of modern psychoanalysis.

Behandlung der Verletzungen und Eiterungen an Fingern und Hand. Von Professor Dr. M. zur Verth, Privatdozent der Universität Hamburg. Second edition. Paper. Price, 8.70 marks. Pp. 164, with 59 illustrations. Berlin: Julius Springer, 1936.

This little volume is a revision of the author's monographs "Introduction to the Treatment of Injuries of the Fingers and Hand" and "The Panaritium," combined under one title. Thirty pages are devoted to various types of compound injuries, two to tendon injuries, one to nerve injuries and forty-eight to fractures and dislocations of the phalanges and the metacarpal and carpal bones. The remainder of the volume, approximately one half, is devoted to infections of the fingers and hand. The work is concise, well written and well illustrated, particularly in its excellent reproductions of x-ray films. The author is one of the few continental surgeons who have carefully studied Kanavel's contributions on infections of the hand and attempted to present his conclusions. His presentation is not always quite in accord with what are understood to be Kanavel's conceptions. For example, in illustrating the incisions for draining an infection involving flexor tendon sheaths of the thumb and little finger and the radial and ulnar bursae (p. 136) the author indicates short bilateral incisions over the volar surface of the little finger instead of a single long incision on the ulnar side of the finger, and a long incision directly over the muscular mass of the thenar eminence. The latter incision, if deep enough to reach the sheath of the long flexor tendon of the thumb, would surely result in division of the important motor

nerve to the thenar muscles. Although one might be critical of a number of more or less important details, the book as a whole deserves praise and commendation. It exemplifies the effort of a thoughtful and industrious surgeon to improve the care of common and important injuries and infections that often result in serious loss of function.

Essentials of Oral Surgery. By Vilray Papin Blair, A.M., M.D., F.A.C.S., Professor of Clinical Surgery in the School of Medicine, Washington University, St. Louis, and Robert Henry Ivy, M.D., D.D.S., F.A.C.S., Professor of Maxillo-Facial Surgery in the Graduate School of Medicine, University of Pennsylvania, Philadelphia. With the collaboration of James Barrett Brown, M.D., F.A.C.S., Associate Professor of Clinical Surgery in the School of Medicine, Washington University, St. Louis. Second edition. Cloth. Price, \$6.50. Pp. 606, with 445 illustrations. St. Louis: C. V. Mosby Company, 1936.

Since the publication of the first edition in 1923, this has been recognized as a valuable text and reference book for students and practitioners. The subject matter is well arranged and the topics are adequately discussed. The authors have successfully avoided one tendency that is common in most textbooks on oral surgery: they have refrained from placing undue emphasis on rare, unusual diseases and treatment and have considered the relative frequency with which diseases occur and gaged their presentation from that point of view. As a result, the reader is given a better understanding of the diseases most commonly met. The chapter on anesthesia is most complete. Indications and contraindications for administering both local and general anesthetics are considered. The authors describe a definite technic for introducing the anesthetic, which, if followed carefully, will bring the desired results. Accidents that may occur and the way to take care of the resulting situations are discussed frankly. The paragraph dealing with ethyl chloride anesthesia could probably be eliminated. After describing its use in several regions, the authors state that "it is not successfully applied to these regions." The chapter on surgical preparation of the mouth for artificial dentures by Dr. Kazanjian is a valuable addition to the book. There is little doubt of the great value of Dr. Kazanjian's contributions to this phase of oral surgery. However, his description of the treatment of abnormally prominent alveolar ridges of the upper jaws is rather more complicated than is necessary. Suturing through the skin and then placing dressings on the face appear to be too involved and dangerous, especially since there is a more simple method that is effective.

Practice of Pediatrics. By Various Authors. Edited by Joseph Brennemann, Ph.B., M.D., Chief of Staff, Children's Memorial Hospital, Chicago, Ill. In four volumes and index volume. Fabrikoid. Loose-leaf. Price, \$63 per set. Various pagination, with illustrations. Hagerstown, Maryland: W. F. Prior Company, Inc., 1937.

The systems of medicine published by the Prior Company already include Tice's Practice of Medicine, Lewis's Practice of Surgery, the Practice of Physical Therapy, Gynecology and Obstetrics, and now comes the Practice of Pediatrics, edited by Dr. Joseph Brennemann, chief of staff of the Children's Memorial Hospital, Chicago. In its make-up, printing, loose-leaf form and other significant typographic aspects, Brennemann's Pediatrics resembles the previously published systems. It has a total of more than a hundred contributors. It differs, of course, from the several previously published systems of pediatrics in being the first in a loose-leaf form. It is planned particularly for the general practitioner and the student rather than for the specialist. It gives perhaps more attention to treatment than has been given by previous systems of pediatrics. The hundred contributors include numbers of American pediatricians, immunologists, psychiatrists, hygienists and other specialists who have been interested in pediatrics.

The history of pediatrics is provided by Dr. Isaac Abt, who prepared a similar contribution, including a history of medical encyclopedias for his own system of pediatrics. In this history pediatrics is considered nation by nation, in the United States, state by state. It is interesting to observe which of the living pediatricians the author has selected for special comment.

The volumes then proceed with an introduction to pediatrics by Blackfan, after which comes the section on heredity and environment, by H. S. Jennings.

It is not possible in the scope of a review such as this to make separate comment on all the articles, and it would be invidious to select any one as deserving of special comment.

The illustrations, some in color, have been wisely chosen and well distributed throughout the work. The volumes following the first, which is of a general character, proceed to discuss the infectious diseases, the diseases of special systems and portions of the human body. It concludes with the nervous system, disorders of speech, and such special topics as orthopedics, arthritis, the appendages, the skin and burns.

The work is well edited. It is easily readable and most easy of reference. Any practitioner requiring a system of pediatrics which is bound to yield valuable dividends in the form of accurate information when needed will find this "Practice of Pediatrics" an excellent investment.

Williams Obstetrics: A Textbook for the Use of Students and Practitioners. By Henricus J. Stander, M.D., F.A.C.S., Professor of Obstetrics and Gynecology, Cornell University Medical College. Seventh edition: A revision and enlargement of the text originally written by J. Whitridge Williams. Cloth. Price, \$10. Pp. 1,269, with 747 illustrations. New York & London: D. Appleton-Century Company, Inc., 1936.

On October 21, 1931, a year after he had completed the revised sixth edition of his textbook, Dr. Williams died at the age of 65. The book had made for itself a definite place in the literature of medicine. It had been widely recommended by teachers in our best medical schools and it has seemed desirable that the work be continued under new editorship. Dr. Stander is professor of obstetrics and gynecology in Cornell University Medical College. He has been aided in the revision of the work by many former pupils of Dr. Williams as well as by other obstetricians, who provided new data and new illustrations. The author points out that in the present edition certain sections are being rewritten, although attempts were made to retain as much of Dr. Williams' last edition as consistent in new developments of obstetrics. Three new chapters have been added, one dealing with hormones as related to pregnancy and the puerperium, one on urinary complications (particularly pyelitis), and the third on anesthesia and analgesia. Many of the illustrations are new and many of the older ones have been retouched, this work being in charge of Miss Elizabeth Broedel under the guidance of her distinguished father, Max Broedel, the well known artist of the Johns Hopkins Medical School. As has already been said, it is well to have this excellent textbook kept up to date and made available for those who first learned their obstetrics from its pages and who still feel that it represents the ideal work for the purpose.

Historical Notes on Psychiatry (Early Times—End of 16th Century). By J. R. Whitwell, M.B., Hon. Lib., Royal Medico-Psychological Association. Cloth. Price, 10s. 6d. Pp. 252. London: H. K. Lewis & Co., Ltd., 1936.

This volume endeavors to trace the process of evolution through which psychiatry passed from early times to the end of the sixteenth century. It includes first the ancient writers, then quotations from the Bible, the Talmud and the Koran, next cases from the classics, the philosophers and the classical medical writers, and finally translations and extracts from great numbers of writers of the earlier periods. As a source book in the early history of psychiatry it represents a fine reference. For the psychiatrist particularly it will offer an interesting exercise in modern diagnosis on the basis of ancient descriptions.

Into This Universe: The Story of Human Birth. By Alan Frank Guttmacher, Associate in Obstetrics, Johns Hopkins University. Cloth. Price, \$2.75. Pp. 366, with 15 illustrations. New York: Viking Press, 1937.

The figurative title to this work is supplemented by the more definite statement "The Story of Human Birth." The book is based largely on questions that have been raised by patients, students and laymen who wanted to know not only the bare facts of childbirth but also the relationship of childbirth to many other activities of life and living. Dr. Guttmacher's previous work, entitled "Life in the Making," was an attractive volume which similarly answered many questions. His literary style is pleasant; his ability to turn exposition into narrative, extraordinarily competent. He has collected a vast amount of interesting material and his chapters on maternal impressions, spontaneous birth, cesarean section and similar subjects will be informative not only to the public but also to many physicians. An unusual feature is the musical scoring of the sounds of pain in labor as contrasted with the expression of pain under ordinary circumstances. The volume is an

extraordinary collection of facts related to childbirth from every point of view. It is supplemented by a well chosen bibliography and a fine index.

On the State of the Public Health: Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1935. Paper. Price, 3s. 6d. Pp. 238. London: His Majesty's Stationery Office, 1936.

In this annual report, Sir Arthur MacNalty makes available the vital statistics of Great Britain for the year 1935. The report is of special interest because it is concerned not only with the records of population and infectious disease but also with maternity and child welfare, the insurance medical service, the relationship of food to health and disease, and, finally, medical research. In the report on the insurance medical service it is pointed out that 8,000,000 insured persons seek medical attendance and that over 50,000,000 attendances are given each year by the doctors. During 1935 there were 157 cases of complaints regarding the adequacy of the service in that year. In 1935 the number of insured persons was 15,869,000 and the number of insured practitioners was 16,600. The total cost, exclusive of administration, was £9,449,900. The authorities are somewhat disturbed over the gradual increase in the prescribing of drugs, which apparently is unexplainable. The authorities feel that a large percentage of the present physicking of the population is wholly unnecessary and that the medical profession of Great Britain is being careless in over-prescribing. It asks the insurance practitioners to give due thought to their responsibility in this matter.

Physiology and Anatomy. By Esther M. Grelshelmer, M.A., Ph.D., M.D., Professor of Physiology, Woman's Medical College of Pennsylvania. Philadelphia. Lippincott's Nursing Manuals. Third edition. Cloth. Price, \$3. Pp. 706, with 401 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1936.

This book has gone into the third edition since July 1932, and each of the previous editions has been reviewed in THE JOURNAL. In this edition, recent information concerning vitamins and internal secretions has been added, and the chapters on the nervous system and the special senses have been reorganized. The general plan of the book, however, is the same as in previous editions; that is, the author endeavors to provide a textbook setting forth in simple language and in many carefully selected pictures the fundamental knowledge of physiology and anatomy. The book is intended primarily for nurses and other nonmedical students. The discussions must necessarily be brief since these two large subjects are covered within the 706 pages of a rather small book, including the pages given over to the glossary in the back and the index. The illustrations have been well planned. In fact, the whole book seems well adapted to the purpose as expressed by the author.

Clinical Psychology: A Handbook of Children's Behavior Problems. By C. M. Louttit, Director, Indiana University Psychological Clinics. With a foreword by L. T. Meigs, M.D., Pediatrician-in-charge, James Whitcomb Riley Hospital for Children. Cloth. Price, \$3.50. Pp. 637, with 21 illustrations. New York and London: Harper & Brothers Publishers, 1936.

There are certain phases of clinical psychology that are particularly concerned with medical problems; for example, those associated with intelligence and special abilities, behavior problems in children, and psychologic problems connected with various organic disabilities, such as speech, blindness, crippling and hearing. The author of this volume has had clinical experience in the University of Indiana at Bloomington and at the James Whitcomb Riley Hospital for Children in Indianapolis. His book reflects that experience as well as wide knowledge of the available literature in his field. By means of well selected case reports he reflects adequately the type of work that confronts the clinical psychologist today. Some of his records in the field of juvenile delinquency are particularly illuminating. The book is an excellent reference work in its field and should be helpful to all who are especially interested in the problems that it concerns.

Yubileyny sbornik nauchnykh trudov Omskogo Meditsinskogo Instituta, 1920-1935. Pod otvetstvennoy redaktsiyei direktora Meditsinskogo Instituta I. I. Sysoeva. [Jubilee Collection of Scientific Works of Omsk Medical Institute, 1920-1935.] Paper. Gratis. Pp. 200, with illustrations. Omsk: The Institute, 1935.

This is a collection of papers published by the institute on the occasion of the fifteenth anniversary of its establishment.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Optometry Practice Acts: Corporate Practice of Optometry Through Licensed Optometrists Lawful in Maryland.—The Castelberg Jewelry Corporation maintained stores for the sale of jewelry, silverware, optical goods, ornaments and other wares of the same general character. In connection therewith, it operated departments for the sale of eyeglasses. To stimulate that part of its business, it furnished optometrical services, employing registered optometrists and supplying them with offices and with instruments and mechanical appliances. The Maryland Association of Optometrists, the Maryland State Board of Examiners in Optometry and the members of that board as individuals brought suit against the corporation to enjoin it from engaging in the practice of optometry in the state. The trial court dismissed the case, and the plaintiffs appealed to the Court of Appeals of Maryland.

It may well be doubted, said the court, whether the board of examiners, as such, has power to institute the present action. Its duties do not include that of enforcing the provisions of the optometry act by civil litigation. Too, the Maryland Association of Optometrists has no property interest affected by the defendant's acts, and its right to sue is not apparent. With respect to the members of the examining board, suing as individuals, there is authority of some persuasive force which sustains their right to equitable relief against illegal competition. The right of any of the plaintiffs to maintain the present action, however, was not determined, because the defendant did not raise the point. The important question, said the Court of Appeals, is whether one who offers to furnish, or does actually furnish through the agency of a registered optometrist, such service as may be required to determine whether persons applying therefor need eyeglasses, and if so what kind of eyeglasses they need, is himself practicing optometry within the meaning of the optometry practice act. The purpose of the act, said the court, is not to protect the financial interests of persons engaged in the practice of optometry; it is to protect the public against injury or harm which might result if ignorant, unskilful or incompetent persons are permitted to offer their services as optometrists indiscriminately. Optometry is essentially a mechanical art which requires skill and manual dexterity. It requires a knowledge of the use of certain mechanical instruments and appliances designed to measure and record the errors and deviations from the normal which may be found in the human eye. It does not require the knowledge and the learning appropriate to professions or callings which deal with causes and conduct rather than with conditions and effects. It is, continued the court, in its nature empirical rather than learned. While literally the word "profession" may be applied to any calling requiring special knowledge of some branch of science or learning, historically and ordinarily it is limited to such vocations as the law, the ministry, medicine, military science, engineering, and the like. Its use in connection with the practice of optometry is merely illustrative of a euphemistic trend apparent in recent years of converting age-old and common callings into "something new and strange," not by changing their characteristics but by describing them in more dignified and sonorous terms.

The provisions of the Maryland optometry practice act sufficiently manifest an intention that no one shall be permitted physically and manually to practice optometry who does not hold the registration certificate issued by the board as evidence of the statutory qualification. The adequate protection of the public health requires no more than that. Beyond that the legislature did not go. The contention is legally unsound that optometry is a learned profession and that a sound public policy denies the right to any one to exploit and commercialize it by furnishing the service incident to the business through the agency of others. There is no public policy which forbids the commercialization of optometry. The business of optometry is that of testing eyesight and selling glasses, and whatever the selling part of it may be called, it is commercial in its nature

and to prohibit its commercialization would be to prohibit the business altogether.

If, the court said, support were needed for the conclusion that the optometry practice act does not prohibit corporations from supplying optometrical services through licensed optometrists, it would be found in the long continued contemporaneous construction given the act by the administrative agencies of the state and by those engaged in the business. For twenty-one years the usage of which the plaintiffs now complain has been widespread and, other than an effort to obtain the enactment of legislation in 1935, no attempt appears to have been made to prevent it. While that fact cannot be accepted, the court said, as conclusive or controlling, nevertheless if the act were open to construction, it would be entitled to serious consideration. The decree appealed from was affirmed.—*Dvorine v. Castelberg Jewelry Corporation (Md.)*, 185 A. 562.

Charitable Hospitals: Liability for Negligence of Nurses.—An operation was performed on the plaintiff's wife in the defendant hospital. Following the operation, an intern ordered the injection of a saline solution. Owing to the negligence of a nurse, a boric acid solution was injected instead of the saline solution, resulting in the death of the patient. The plaintiff thereupon sued the hospital. The trial court gave judgment for the plaintiff, and the court of appeals reversed that judgment and remanded the cause. On the motion of both parties, the case was certified to the Supreme Court of Ohio.

There was ample testimony, said the Supreme Court, that the hospital was operated as a public charity. It was therefore not liable for injury to a patient resulting from the negligence of a nurse, unless it failed to exercise due care in the selection or retention of the nurse who caused the injury. The burden of showing such lack of care rested on the plaintiff. The record in the present case showed that the nurses in charge of the patient were graduate nurses, with long training and experience. The plaintiff presented no evidence that the hospital authorities had been lacking in care in selecting or retaining them and certainly, said the court, the hospital authorities should not be charged with lack of due care when the incompetence of the nurse appeared for the first time after the operation. In view of these circumstances, the court concluded, the court of appeals should not have remanded the case for a new trial but should have rendered final judgment for the hospital. The judgment of the court of appeals in remanding the case was therefore reversed and judgment rendered for the hospital.—*Kovar v. Lakeside Hospital (Ohio)*, 2 N. E. (2d) 857.

Malpractice: Refusal of Physician to Accept Patient.—The plaintiff was an employee of the Milledgeville State Hospital, an institution owned and operated by the state of Georgia. The defendant, a physician, was the superintendent of the hospital. The report of the case does not disclose the nature of the plaintiff's illness but apparently she applied to the defendant for relief and he refused to treat her. Thereafter she instituted a malpractice suit against him. The trial court dismissed the action, and the plaintiff sought a reversal in the court of appeals of Georgia, division 1.

The plaintiff's petition, said the appellate court, failed to show that the relationship of physician and patient existed between the plaintiff and the defendant. On the contrary, it repeatedly alleged the refusal of the defendant to do anything for her. Merely because the defendant was a physician and knew of the condition of the plaintiff would not devolve on him the duty of rendering medical care to her, even though the plaintiff applied to him for treatment. There is no rule of law that requires a physician to undertake the treatment of every patient who applies to him. "An act requiring a license before a person practices medicine is essentially a preventive, not a compulsory measure, and one who has secured a license according to statute is not liable for damages alleged to result from the refusal to take a case." 21 R. C. L. 379; *Hurley v. Eddingfield*, 156 Ind. 416, 59 N. E. 1058, 53 L. R. A. 135, 83 Am. St. Rep. 198.

Nor did the plaintiff automatically become a patient of the defendant because of their respective relationships to the hospital. While it is a general rule that "the physicians and surgeons of a hospital, public or private, enter into the relation of physician and patient with every patient brought into the

hospital as soon as he is brought in," 21 R. C. L. 376, there was no evidence that the plaintiff was a patient in the hospital. The defendant was required "to reside constantly on the premises, and devote his professional services exclusively to the use of the Hospital. . . . To discharge all duties in any way connected with the restoration to health or sanity of the inmates." The statute relating to the hospital provided that "lunatics, epileptics, idiots, and demented inebriates, may become inmates of the hospital and shall be admitted to, and discharged from, the Hospital under such rules and regulations as the Board of Control shall prescribe." The petition filed by the plaintiff, however, failed to allege that she came within any of the enumerated classes.

The trial court did not err, in the opinion of the appellate court, in dismissing the petition, and the judgment of the lower court was affirmed.—*Butterworth v. Swint (Ga.)*, 186 S. E. 770.

Charitable Hospitals: Liability to Visitor; Indemnity Insurance as Affecting Liability.—The plaintiff's husband was a pay patient in the defendant hospital, an institution incorporated and operated for charitable purposes. On a visit to her husband, the plaintiff slipped on a floor and fractured her left wrist and hip and thereafter sued the hospital for damages. The hospital interposed as a defense, among others, the fact that it was a charitable institution. Admitting the status of the hospital and that its trust funds could not be used to satisfy any damages that might be awarded, the plaintiff alleged in her pleadings that the hospital had taken out a liability insurance policy, that the recovery of damages to which plaintiff was entitled would be paid by the insurance company, and that therefore none of the trust funds of the hospital would be dissipated. The defendant demurred to this pleading. The trial court ruled that the existence of the insurance policy did not render the hospital liable in any case in which it was not otherwise liable for its negligence and that, since the plaintiff had admitted that the trust funds of the hospital could not be used to pay damages, the defendant's demurrer would have to be sustained. The plaintiff thereupon appealed to the Supreme Court of Tennessee.

The fact that the defendant carried a liability insurance policy, said the Supreme Court, gave the plaintiff no additional rights and imposed no additional obligations on the defendant. While the record showed that the plaintiff's husband was a pay patient in the hospital, the court was unable to see that that fact had any bearing on the liability, if any, of the hospital to the plaintiff, for the injuries complained of did not arise out of any treatment to the patient. Furthermore, the court said, the exemption extended to a charitable institution for a tort is not changed by reason of the fact that the patient pays for the services rendered. The determinative question in this case, the court continued, is whether the defendant was wholly exempt from liability, irrespective of the fact that the plaintiff was not a beneficiary of the charity. The rule of exemption of charitable institutions, said the court, is by no means of universal application. In Minnesota it is held that charitable institutions are liable for their negligence as are other institutions. *Geiger v. Simpson Methodist-Episcopal Church*, 174 Minn. 389, 219 N. W. 463. In Tennessee, a broad rule of nonliability was laid down in *Abston v. Waldon Academy*, 118 Tenn. 24, 102 S. W. 351, but that decision was later criticized in *Love v. Nashville Agricultural and Normal Institute*, 146 Tenn. 550, 243 S. W. 304, in which case recovery was permitted against a charitable institution for creating a nuisance, the pollution of a spring. Furthermore, in *Gamble v. Vanderbilt University*, 138 Tenn. 616, 200 S. W. 510, the court recognized the university's liability for a tort committed by one of its servants. In the present case, therefore, the court failed to see the justice in exempting charitable institutions from liability for injuries sustained by one who was not a beneficiary of the trust. Taking this view of the matter, the court said, the defendant's plea of exemption on the ground that it was a charitable institution was not a sufficient defense and the trial court should have so held and should have proceeded to try the case on its merits. The judgment of the trial court was therefore reversed and the case remanded for trial.—*McLeod v. St. Thomas Hospital (Tenn.)*, 95 S. W. (2d) 917.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

- Vaginitis of Children: Review of Literature. R. A. Benson and A. Steer, New York.—p. 806.

Prognosis of Glomerular Nephritis in Childhood.—Snoke points out that the existence and the persistence of latent glomerular nephritis in childhood, as in adult life, usually escape detection when quantitative examination of properly concentrated urine is not made. Glomerular nephritis commonly, if not invariably, enters a latent stage after the initial stage. The initial stage often is overlooked when gross hematuria or fulminating symptoms are absent. Latent glomerular nephritis may terminate in healing or may pass on to the degenerative stage or to the terminal stage, and its duration is enormously variable. The later stages frequently do not occur till some period of adult life. Between 1920 and 1936, 154 children with glomerular nephritis have been followed: fifty-seven of these have now recovered, thirty-three are dead and sixty-four still have active nephritis, thirty-five of whom have been in that stage for more than two years and six for more than ten years. With only two exceptions, both slightly doubtful, no instance of nephritis lasting more than two years has ended in recovery. An eventual fatality rate of 40 per cent for glomerular nephritis is a conservative estimate. The prognosis for the successive stages of glomerular nephritis—active, latent, degenerative and terminal—is progressively worse, the last named being uniformly fatal. The age of onset (or detection) has no significant relation to prognosis. Hypertension and increased amounts of blood urea have similar significance and tend to parallel each other; in the initial stage they have no relation to prognosis, but when they appear in the

later stages they supply the first indications that the patient is entering the terminal stage of renal insufficiency. The value for blood urea does not become abnormally high as a general rule until 50 per cent or more of the renal tissue fails to function. Glomerular nephritis cannot be proved to be healed until repeated quantitative examinations of concentrated urine over a period of at least one year have been normal.

Convalescent Serum in Prevention of Chickenpox.—Lewis and his associates inoculated 10 cc. of pooled convalescent serum into twenty-three children exposed to chickenpox from one to three days previously. Nineteen children who had been exposed to chickenpox in the same wards received no inoculations and served as controls. Twenty-one children, or 91 per cent, of the treated group contracted chickenpox; eighteen children, or 95 per cent, in the untreated group had the disease. It was somewhat more severe in the children receiving convalescent serum than in those not receiving serum.

Prophylaxis of Whooping Cough.—Meader treated 115 children from 1 to 6 years of age with 10 cc. of blood serum from persons who had recovered from whooping cough. Whooping cough developed in thirty-seven, or 32.2 per cent. Whooping cough developed in eight children on the first day after the serum was given. The record in these cases should not discredit the value of the serum. The fact that the disease developed during the first six days after administration of the serum should not be counted against the serum. Twenty-one patients should therefore be excluded. Failure should be charged against the serum in only sixteen of the thirty-seven cases. For controls, 183 children of the same ages were used. These children were exposed to whooping cough but were not given blood serum from persons who had recovered from this disease. Whooping cough developed in 121, or 66 per cent. When comparable groups of treated and untreated exposed children are compared, about 72 per cent of those treated with 10 cc. of pooled convalescent serum will be protected from the disease. The incubation period is so long that while one of two children in a given family who receive the serum prophylactically at a fortuitous moment will be protected, another receiving the serum in the latter part of the incubation period will contract whooping cough, apparently having obtained no protection. The most favorable results are obtained with children in the first three years of life. This serum will therefore probably never be as spectacular in its effects as similar convalescent serum is for scarlet fever, for which a short incubation period prevails.

Results of Induction of Labor in Cases from Private Practice.—After analyzing 750 cases of induced labor from private practice and comparing them with a consecutive, contemporary series of cases in which labor was not induced,

Mathieu and Holman reached the conclusion that the maternal and fetal morbidity and mortality were not increased by induction. Induction of labor was successful in 98 per cent of the cases. Induction was apparently not responsible for the occurrence of any pathologic condition during labor, delivery or the puerperium. In the last 550 inductions quinine was not used, and the results were apparently not affected by its omission. In the last 351 cases, if labor did not start after three or four injections of 3 minims (0.2 cc.) of solution of posterior pituitary, the membranes were artificially ruptured during induction if there were no contraindications and if they had not already ruptured. In the last 114 cases castor oil was omitted and pentobarbital was given before the hypodermic injections were started. Omission of castor oil in no way affected the success of induction. Pentobarbital has been advantageous in keeping the patient tranquil and free from pain, has not interfered with the success of the induction and has not affected the vital statistics unfavorably. In the 750 cases of induced labor there was no instance of abruptio placentae or of fetal death due to cerebral injury or birth injury. There was one instance of prolapsed cord, in a patient whose membranes ruptured spontaneously.

- Velamentous Insertion of Umbilical Cord. A. J. Whitehouse, Lexington, Ky.—p. 527.

Diabetes Complicating Pregnancy.—White believes that the incidence of spontaneous abortion may be reduced by more accurate control of diabetes. Toxemia and eclampsia occur with great frequency, particularly in the youthful type of diabetes. Related to these complications is the common complication of the diabetic pregnancy, a giant fetus. Deaths in the neonatal period are largely due to congenital defects which are beyond therapeutic control, to hypoglycemia which can be corrected and to asphyxia, to which the infant of the diabetic patient is undoubtedly more liable than that of the nondiabetic, because of the greater danger of toxicemic and diabetic acidosis. The treatment of the diabetic patient during pregnancy must be individualized. The diabetic woman should not have numerous pregnancies, because diabetes carries with it a morbidity hazard; but, most important of all, the potentiality of developing the disease is inherited.

Diagnosis of Abruptio Placentae and Treatment with Wheat Germ Oil.—In a series of forty-four cases of spontaneous abortion, Shute observed that 73 per cent showed evidences in the blood serum of deficiency of vitamin E. It is now generally recognized that vitamin E has great prophylactic and therapeutic value in the treatment of abortion; therefore he began to study the corresponding use of a vitamin E preparation in

cases of abruptio placentae. Such an oil must be kept cold and be not more than eight weeks old. Patients first seen when placental detachment is already complete or nearly complete offer little excuse for anything but the classic measures used for such an emergency. However, a closer search for true uterine tenderness during pregnancy, combined with an early test of the blood serum for the presence of the specific hormone-vitamin imbalance, would be a great step in preventing the occurrence of such severe cases. It has been the author's experience with the less severe cases that, when properly and adequately saturated and kept saturated with vitamin E (as determined by clinical evidence and repeated tests of the serums), they have not progressed to a severe stage of placental detachment with death of the fetus. In approximately twenty hours, an adequate massive dose of from 8 to 12 drachms (32 to 48 Gm.) of bulk wheat germ oil has completely abolished the characteristic circumscribed area of uterine tenderness. The accompanying severe sacral backache and uterine cramps have subsided as rapidly. When uterine hemorrhage has been present, it has responded promptly as well. Stopping the oil therapy has often been followed by a recurrence of uterine tenderness and bleeding, which, in turn, have disappeared on further vitamin E therapy. No case recognized early and treated adequately has gone on to the severe classic type. The author's best results have been obtained in women who showed little or no evidence of an associated toxemia.

- O'Connor Cinch Operation Technic. S. A. Durr, San Diego, Calif.—p. 178.

Experimental "Exophthalmos" in Dogs.—Essex and Corwin measured the position of the eye and found that anesthetics such as sodium amytal, pentobarbital sodium and a preparation of chloral dextrose administered intravenously, cause marked exophthalmos, surgical ether anesthesia produces slight exophthalmos, and ephedrine, tyramine and electrical stimulation of the vagosympathetic nerve of dogs anesthetized with certain intravenous anesthetics cause the eye to advance almost to the position seen when the animal is in a conscious state. In the unanesthetized animal, ephedrine and tyramine in appropriate doses do not produce an exophthalmos worthy of note. Tyramine causes the muscular cone of the eye of a dog under anesthesia with pentobarbital sodium to constrict in an identical manner and for a period comparable to that resulting from electrical stimulation of the cut vagosympathetic nerve. Repeated daily doses of tyramine do not cause exophthalmos in normal or experimentally thyrotoxic dogs.

Arch. of Physical Therapy, X-Ray, Radium, Chicago

18: 65-128 (Feb.) 1937

- Iontophoresis of Varicose Ulcers. J. Kovacs, New York.—p. 103.

Short Wave Diathermy in Treatment of Pulmonary Infections.—Fiandaca shows the efficacy of short wave therapy by reporting twelve cases of pulmonary infections, only two of which were not benefited. Hemoptysis occurred in one case and the failure in the other one is explained by the distribution

of the bronchiectatic suppurative process. Hemoptysis can be corrected and avoided by the initial administration of weak doses administered over a longer period. Examination of the cases under consideration discloses that metapneumonic abscesses are the most sensitive to short wave therapy, while those of bronchiectatic origin are the most resistant. In three cases of bronchiectasis without abscess treated by short wave the results were merely a slight and temporary benefit. The appearance of vomitus marked the beginning of symptomatic improvement in three cases. Of the diverse symptoms pain, as a general rule, is the first to disappear. Fever at first becomes worse, then intermittent and finally decreases and disappears entirely. Expectoration is the most persistent phenomenon, at first losing its fetor, then the purulence, and finally remaining as seromucous sputum for some time. Strong dosage is essential if a pulmonary infection is to be cured, but treatment should be initiated with great care and with small dosage when this form of therapy is administered as a last resort. Observations do not appear to justify confirmation of a specific action of the short wave in the determination of bacterial form, especially if the multiplicity of the etiologic factors in every pulmonary abscess is considered. It appears more probable that the beneficial effect of short wave diathermy on pulmonary abscesses is ascribable to the anatomic structure and function of the lungs, which, according to Schliephake, present a special suitability to this kind of treatment, as compared with other structures of the human system. The alveolar structure of the lung through which the energy is radiated presents a lessened resistance, while the pulmonary ventilation and the rich vascular net prevent undue concentration of energy in the form of heat. These characteristics facilitate the application of relatively intense doses to a normal lung, but this would prove of little value for the control of a lesion with its break in the continuity of the spongy tissue and reduced blood supply. Naturally any such lesion would present intense reaction to a large dose. Pulmonary tissue proper would obtain a beneficial effect from stronger doses of short wave diathermy without at the same time producing lasting damage to the normal structures.

Apple Powder in Treatment of Diarrheal Conditions.

—Manville and his associates declare that the apple, since it contains acids, sugars and starch, cellulose and hemicelluloses, vitamins and pectin, occupies first place as a therapeutic agent of the fruit type. Tannic acid, because of its astringent effect, forms a protective coating on the mucous membrane. The tannin content of the apple is unaltered in the preparation of the powder. Its concentration, however, is increased, since it

requires 100 Gm. of raw apple to make 15 Gm. of powder. Malic acid, as well as the other organic acids, is not appreciably altered in the preparation of the powder. There is some evidence to the effect that malic acid possesses a definite antiseptic value. The available sugar content of the apple is a little more than 12 per cent. It is composed of dextrose, sucrose, fructose and a small amount of starch. Aside from its caloric value, sugar increases the colloidal properties of pectin. The cellulose content of the fresh apple is slightly more than 1 per cent, while that of apple powder is a little more than 8 per cent. The vitamins contained in apples are limited to A, B and C. The chief value of the apple in the treatment of diarrheas and dysenteries appears to reside in the pectin component. It is partly due to their absorptive quality that pectins are able to fix bacilli and toxins and thus render them inert and to take up the fluid secretions and thereby convert a fluid stool into a formed one. Pectin removes the irritants and by providing bulk stimulates a normal physiologic peristalsis. Pectin is also a good buffer and, through the medium of this activity, is able to keep the fluctuations in the reaction of the intestinal contents within narrow limits. It also acts to some extent as a protective colloid. Apple powder has its greatest application in infantile conditions but is becoming definitely useful in the treatment of gastro-intestinal diseases in the adult.

- *Diagnosis of Pulmonary Tuberculosis in Its Preclinical and Early Clinical Stages. H. W. Hetherington, Philadelphia.—p. 379.

Early Diagnosis of Pulmonary Tuberculosis.—Hetherington points out that case finding is the diagnosis of tuberculosis in its early clinical and preclinical stages. The dispensary method and the survey method are the two types of case finding procedures. The survey method is applicable to groups, such as high school, college and university students, to nurses and to industrial employees. It consists of a tuberculin test, roentgen examination, occasionally fluoroscopic examination and the application of clinical procedures to give additional information. The dispensary method consists in the examination of individuals with symptoms suggesting tuberculosis and the institution of prophylactic care and treatment when a diagnosis is made. It is among the contacts of sputum positive tuberculosis that new cases of tuberculosis are most likely to be found. Here the tuberculin test is an index of the infection of other members of the household. Roentgen examination is used to determine the presence of a lesion and to define its extent and characteristics. Members of households in which clinical tuberculosis exists should have periodic examinations, with roentgen examination at appropriate intervals. The tuberculin test and roentgen examination is valuable not only in the diagnosis of tuberculosis in the early clinical and preclinical stages but also in excluding this diagnosis.

Control of Syphilis and Gonorrhea.—Burney enumerates how every physician can do his part in the control of venereal disease. 1. Reporting of all cases of venereal diseases is a necessary procedure just as it is in typhoid or tuberculosis. If sources and contacts are to be found, examined and treated

and if infectious cases lapsed from treatment are to be returned to the physician, case reporting must be done. 2. It is essential that the physician follow proved, accepted standards of treatment in early cases to render the patient noninfectious when continuous and adequate treatment is so important. 3. The value of a routine serologic test is beyond question. In pregnancy, it must be a part of the first examination—rich or poor patient, early or late stage. 4. The physician-patient relationship is most important, something that cannot be obtained outside of private practice. 5. The physician must take his rightful place as an educator and teacher in all health problems. It is far better for him, with his scientific knowledge and experience, to tell young people about venereal diseases than for some socially minded but uninformed person to present a lot of untruths and misstatements which only confuse. 6. Cooperation with state and local health departments will be both beneficial and helpful in the combined efforts to control venereal diseases. Health departments do not take practice away from the physician; on the contrary, they should add to it through their many and varied educational programs. The physician should make use of them for his free laboratory service, for consultation and for any information he may desire and, in return, help them by his fullest cooperation. This is not a problem for one man or for one group; it can and must be a united effort.

Hypertonic Dextrose Therapy in Cardiovascular Diseases.—In reviewing the benefits of intravenous dextrose therapy in cardiovascular disease, Meyer mentions certain precautions. The solution should be warmed to body temperature, and only a solution made and tested by a standard pharmaceutical house should be used. Any concentrated solution is extremely irritating to subcutaneous tissues, and a 50 per cent concentrated solution almost invariably causes sloughing. Too rapid administration of even small amounts is attended with a definite drop in blood pressure, and pulmonary edema is another possibility when the compensation is in delicate balance. Venous thrombosis rarely occurs if the needle is inserted some little distance into the vein lumen. Continued daily injections of concentrated solutions will produce a secondary anemia. This was demonstrated experimentally in five apparently healthy persons who were given a series of hypertonic injections with the counts being made on venous blood. Hydremia will explain the initial drop, but carefully made slides showed a disintegration of red cells to a much greater extent ten minutes after the dextrose than in those before administration. The really valuable attributes of dextrose in cardiovascular diseases are well established. It has been proved experimentally that 50 per cent concentrated solutions increase the coronary rate of flow from 10 to 100 per cent and that the response is always obtained with repetition. In addition to its vasodilatory action, it has been shown experimentally that there is a marked increase in the glycogen reserve in the myocardium. By so doing the size of the resultant infarction, when a sudden occlusion results, should be materially reduced. In arteriosclerosis with cardiorenal failure characterized by hypertension, edema and diminished urinary secretion, concentrated dextrose has been used extensively. Theoretically it should offer good insurance against a too rapid degenerating myocardium and kidney tissue. In addition, its diuretic action is beneficial to the patient's comfort. Alleviation of subjective symptoms such as heart consciousness, headache, dizziness and mental cloudiness is marked. Chronic congestive heart failure due to arteriosclerotic degeneration also responds favorably to this type of therapy. Improved circulation through the coronary arteries and the increased food supply to the myocardium accounts for symptomatic relief.

The Lymphatics and Lymph.—McMaster points out that vital dyes injected intradermally enter lymphatic capillaries directly, rendering them visible, and appear later in the draining lymphatic trunks as colored streamers. The method yields consistent results when tested under physiologic conditions known to increase or decrease lymph flow. In the horizontally placed normal limb at rest there is slight lymph flow. In a normal leg or arm hanging downward, lymph flow ceases although fluid in the limb increases. When a previously dependent arm is raised above the head, or when the foot of a seated subject is propped on a table, lymph flow in the raised limb becomes active. It ceases in the skin of an arm subjected to partial obstruction of the veins by pressure from without, but very active lymph flow appears during the reactive hyperemia that follows on the release of venous obstruction. It is still greater following release of total circulatory obstruction and seems to be the same whether or not the limb has been engorged previously with blood. In the ischemic patches which appear in the skin of a limb during total circulatory obstruction (Bier's spots) the lymphatic capillaries are definitely and considerably constricted, whereas they are slightly dilated in the purple, congested regions of the skin round about. On release of obstruction there occurs a strikingly rapid, equal lymphatic drainage from both regions. When dye is injected intradermally and the skin sucked, much of the foreign material is driven into the lymphatics draining the injected area.

Lymphatics and Lymph Flow in Edematous Skin.—McMaster performed more than 100 tests on twenty persons with cardiac disease and edema of the lower limbs. The tests yielded evidence of stagnation of lymph and incompetence of the lymphatics. In contrast to the stagnation of lymph in the edematous skin of patients suffering from cardiac disorder there exists a greatly increased cutaneous lymph flow in patients with nephritic edema. Local intradermal injections of dye have disclosed the fact that the skin lymphatics in regions of cardiac edema are patent, full of fluid and much widened. Intercommunication between them is ready and dye escapes from them more rapidly than from the vessels of normal skin. A retrograde distribution of dye by way of the lymphatics often occurs and it may pass unseen along the deeper channels to emerge in the skin at unexpected, distant situations. A valvular incompetence of the lymphatics consequent on dilatation would appear to be the cause of these phenomena. In regions of cardiac edema lymph stagnates, despite the fact that the channels are open. In nephritic edema the lymphatic capillaries are wider than normal but not as wide as in cardiac edema. No sign of incompetence of the valves is to be observed. Instead

lymph flow is considerably greater than normal, even when edema fluid is accumulating. It is greater in the periods of fluid equilibrium also and extraordinarily rapid in periods of diuresis.

Complement in Serodiagnosis of Syphilis.—Koopman and Falker assert that the quantitative relationship of complement to hemolysin is of more than academic importance. It has a direct bearing on the accuracy and consistency of all complement fixation tests. It is also the fundamental factor needed to solve the problem of the effect of the natural hemolysin in patients' serums on complement fixation results. The experiments that they outline demonstrate that in complement fixation reactions an excess of one reagent does not compensate for a deficiency of the other, and any method which is based on the theory of compensation cannot produce reliable or consistent results. A titration that is useful in disclosing the relationship existing between complement and hemolysin is planned so that various amounts of complement from a minimum (0.01 cc.) to a maximum (0.1 cc.) are allowed to act with various amounts of hemolysin from a minimum to a maximum. The effect desired will be more clearly shown if the complement and hemolysin are diluted so that each solution contains one unit in a volume of 0.1 cc. The cells are a 5 per cent suspension, and 0.1 cc. is used in each tube. The total volume is 0.5 cc. This titration should be allowed to remain in the water bath at 37 C. for at least one hour.

Trichinosis with Eosinophils in Stools.—Baumgartner and Cowles found eosinophils in the stools of two patients who had had diarrhea for weeks. A history of eating raw sausage just before this diarrhea began was obtained in both; they had high eosinophil percentages in blood smears at that time and now gave positive skin and precipitin reactions to trichina antigen. Four patients known to have had trichinosis also gave positive skin and three of these positive precipitin tests. One patient, an Italian girl, daughter of a known trichinosis patient, had an eosinophilia at the time of her mother's illness and now gave a markedly positive skin and precipitin test. Nine patients with no record of an eosinophilia and a negative history for trichinosis all gave negative skin tests and three of these had a negative precipitin test. Three patients in whom an eosinophilia (10, 11 and 23 per cent) was found in routine blood counts gave positive skin tests and one of these a negative precipitin test. The securing of positive skin tests in cases of eosinophilia may be accidental, since McCoy and others also noted this, but a further study of such cases with skin and precipitin tests is indicated.

Iron Retention in Infancy.—Stearns and Stinger determined the quantities of iron actually retained by fourteen infants from 7 to 54 weeks of age who were given various types of feeding. One infant was given human milk; the basic milk formula for the others consisted of evaporated milk containing a cod liver oil concentrate. The milk feeding was acidified with citric acid and contained 6 per cent of added carbohydrate, a dry dextrin-maltose mixture. Distilled water was used for making up the feedings. Each infant was given 2 ounces (60 cc.) of orange juice daily. Egg yolk, potassium and iron salts, when fed, were added to the formula; spinach and cereal were fed separately. During the experimental periods the day's feeding for each infant was quantitatively prepared and an aliquot saved for analysis. The baby given human milk was never in negative balance although the retention was always small. Those given cow's milk feedings alone lost an average of 0.05 mg. of iron daily. The age of the infant had no apparent influence on the ability to retain iron. Neither egg yolk nor spinach, in the amounts given, increased the iron retention. The retention was definitely increased when the infants were given the special iron-rich cereal or ferric ammonium citrate. No consistent relationship was observed between the iron retention and the intake of potassium, calcium or phosphorus. It appears that an intake of approximately 0.5 mg. of iron as food or as soluble salt per kilogram of body weight is necessary to insure a retention of iron, and an intake of from 1 to 1.5 mg. per kilogram permits ample retention. Ample retentions were observed with these intakes of iron, whether the source of iron was from a special cereal and egg or from ferric ammonium citrate.

Intrathoracic Anatomic Readjustments Following Complete Ablation of One Lung.—Rienhoff presents his analysis of sixteen cases, in twelve of which a complete pneumonectomy was performed and in two a posttraumatic atrophy of the left lung had occurred; in the remaining two there was a congenital absence of one lung. The restitutional compensatory mechanism following total or partial removal of a lung is based on the readjustment and adaptation of the thoracic cage and diaphragm on the operated as well as on the unoperated side, on the com-

the skin test. This is a smaller percentage than is found among normal women at or about full term. Contrary to experience in scarlet fever, none of the positive reactors gave a negative reaction when retested subsequently at an interval ranging from six to thirty-seven days. The filtered peritoneal exudate of two fatal cases of puerperal peritonitis in which an intense scarlatiniform rash had occurred during life was found to contain an erythrogenic toxin of considerable potency when tested on human beings, and this toxin was neutralized by standard antitoxin. With one of the filtrates a sharp febrile reaction also resulted from intradermal injection. A serum to be of value as a prophylactic remedy against puerperal infection must be capable of preventing invasion by any one of many types. Until there is unmistakable evidence of the curative value of serum given after the beginning of experimental infections of animals (i. e., in circumstances comparable to those of human infections), it would seem prudent to withhold serum treatment in human cases.

Observations on Etiology of Influenza.—The attempts of Fairbrother and Hoyle to isolate by ferret inoculation a virus from cases of sporadic influenza and other diseases during an interepidemic period in the Manchester district have given negative results. Studies of normal human serums in the area have shown that neutralizing antibodies against both human and swine influenza viruses are present in many of the serums. A complement fixation test has been developed for the study of the antibody content of human serums and the results obtained indicate the presence of a common antigenic factor in the human and swine viruses. The antigen concerned with complement fixation is distinct from that involved in the neutralization test. Attempts to isolate virus from material collected during an outbreak of epidemic influenza in Leningrad have given negative results, although it is possible that the delay in transit of the material may explain this failure. A study of a small number of serums collected after the epidemic has provided some evidence that the virus may have been the causal agent.

Carbaminoylcholine in Postoperative and Postpartum Retention of Urine.—Moir used carbaminoylcholine in the treatment of thirty-eight cases of postoperative or postpartum retention of urine. The drug is often remarkably successful in causing the patient to void urine naturally and is worthy of trial in patients for whom catheterization would otherwise be necessary. Its most successful use is after abdominal section or after a simple vaginal operation. It is least successful in patients suffering from overdistention of the bladder—especially after childbirth, and in cases in which there is mechanical obstruction to the passage of urine. One of the chief errors to guard against is the assumption that a patient has completely emptied her bladder by the micturition induced by the drug. Often the evacuation is only partial. Side effects (slightly accelerated pulse, nausea, faintness and a feeling of warmth) are seen in about a third of the cases but are seldom serious. The dose, 0.25 mg. of the pure substance dissolved in 1 cc. of fluid, was usually given intramuscularly.

*First Attempts at Heteroplastic Medullary Grafts in Man in Injuries of Peripheral Nerves. A. Gosset and I. Bertrand.—p. 197.

Heteroplastic Medullary Grafts.—More than two years ago Gosset and Bertrand reported their experiments in grafting pieces of the spinal cord on a severed peripheral nerve in animals. In the succeeding two years they continued their experiments also on man. Twelve such graftings were done in France, of which four were by the authors. The animal used is the adult rabbit or the cat weighing from 5 to 6 pounds which is killed by severing its carotid artery under short anesthesia. Under strict asepsis the dorsal part of the spine is resected. The dura mater is carefully laid bare, without the slightest injury to it or to the underlying cord, which is dissected. The cord together with its spinal segment is immersed in a 20 per cent solution of formaldehyde. The next day it is easy to free the cord from its bony attachment and then it is again immersed in a fresh 20 per cent solution of formaldehyde. It can thus be preserved for a number of months. A few days before using it the piece of cord is washed in sterilized salt solution, which should be renewed as often as there are traces of formaldehyde left. It is then immersed for two or three days in 90 per cent alcohol. The authors' first experiment was on an interrupted radial nerve at the elbow. The graft was united with a silk suture to the upper end of the nerve and with three silk sutures to its lower end. Two months later, dorsal extension of the wrist was possible. About a year later this activity became much stronger, but extension of the fingers and abduction of the thumb were incomplete. There is also hypoesthesia in the area of the radial nerve. About fourteen months after the operation, weak electrical responses were demonstrated. The procedure in the other cases was similar. In contrast with the usual well known slowness of recuperation, this intervention shows rapid regeneration. Of course, part of the success must be attributed to the youth of the patients. The authors assume that there is a vicarious substance in the dead graft which is capable of activating the progression of the axis cylinder. This is astounding in view of the fact that the living central nervous substance prevents the regeneration of the axis cylinder. Physicochemical processes seem to play an important part in either accelerating or retarding the recuperative forces in a degenerated nerve.

*Action of Gastric Juice on Gastric Secretion. Léon-Meunier.—p. 276.

Thyroid Osteosis and Spontaneous Fracture in Exophthalmic Goiter: Case. F. Gottlieb and M. Schachter-Nancy.—p. 277.

Action of Gastric Juice on Gastric Secretion.—The treatment of gastric ulcer by injection of various substances has been the subject of numerous articles. All these reports show only a restricted duration of observation and a consistent admission of the sedative action of the injected material. Léon-Meunier utilized Loeper's experiments with pepsin because it is a positive colloid and as such has, like proteins, shock properties, and also because it is a specific colloid and can be used like glandular extracts. Idiosyncrasies, which occurred even when feeble doses were used, prompted the author to employ the patient's own pepsin. The fasting patient receives an intragluteal injection of 0.5 cc. of a solution of histamine of 1 mg. per cubic centimeter. After a few minutes, when the patient has symptoms of vasodilatation, he is given orally 50 cc. of physiologic solution of sodium chloride. The gastric mixture is then extracted from the patient in a horizontal position, filtered, submitted to fractional sterilization at 140 F. and neutralized with a sterile isotonic solution of sodium bicarbonate. Subcutaneous or cutaneous injections are given in the buttocks daily in amounts of 1 cc. of this solution. During this treatment the patient undergoes no change of diet. By injecting histamine without a test meal the author believes that errors due to residual fluids have been eliminated. This enables him to determine the constant acidity of the gastric juice, which

is a true picture of the gastric mucosa in action. Through the injection of the patient's own gastric secretions the author obtained a diminution of pain in hypersecretion accompanied or not by an ulcerous lesion. This diminution of pain runs parallel with a decrease in acidity estimated as constant acidity by the method of double dilution. These phenomena are a result of desensitization of the patient, causing a decrease in acidity and a consequent change in the element of pain. But they do not allow the deduction of anatomic cure of the ulcer.

*Yellow Fever and Antiamarillic Vaccination. E.-L. Peyre and P. Fricaud.—p. 291.

Pulmonary Lesions in Country Schools. M. Gillard.—p. 294.

Yellow Fever and Antiamarillic Vaccination.—Peyre and Fricaud, of the French colonial army, describe nine cases of meningeal accidents occurring a few days after vaccination against yellow fever. A noncommissioned officer received two injections in three weeks. Two days after the second injection he presented general urticaria, vomiting, debility and raised temperature but no albuminuria. He had tremors in both arms, especially the right, diffuse hypertonia, myoclonic agitation and cogwheel sign. There was progressive improvement, but relapse occurred ten weeks later. The tremors of the right arm hindered his work and, because his general condition remained deficient, he was invalided home. Two groups of symptoms must be considered in almost all cases, one dealing with visceral disorders caused by a virus which is little pathogenic for man. The other group is caused by the neurotropic virus able to bring forth an encephalitic reaction after a simple subcutaneous injection. A fatal case of yellow fever in a previously vaccinated subject was of the latter type: onset with fever, pain in the back and epigastrium, alimentary, bilious and hemorrhagic vomiting, metrorrhagia, subcutaneous ecchymoses and albuminuria; after four days improvement and icterus, but the next day exacerbation of symptoms and death of amarillic hepatitis. This case and some tests made on rhesus monkeys seem to throw doubt on the efficacy of yellow fever vaccination, and its inconstant action on mice has raised doubts as to the fixity of the neurotropic virus. In four recent cases albuminuria was found to be of less reliable diagnostic value. Instead, azotemia was a faithful prognostic guide. It seems to be the result of considerable disassimilation of nitrogenous substances of the organism which have an extrarenal bearing on the parenchyma of the liver. This bearing is evidenced also by hypochloremia and some authors have demonstrated that, whenever the elimination of chlorides is considerably diminished in infectious diseases, as in yellow fever, there is retention of injected chlorides during the disease, probably for the neutralization of azotemia, and an increased elimination at the beginning of convalescence. It was therefore encouraging to notice an increase in elimination following injections of sodium bicarbonate and chloride, and, in one case, of hypertonic saline solution. The blood urea rose to 1 Gm. at the critical point on the sixth day, to come down to 0.4 on the ninth day. The pathologic physiology of yellow fever is little known as yet and its vaccination has no constant action.

Juvenile Calcaneal Apophyseal Dystrophy.—According to Leinati, juvenile calcaneal apophyseal dystrophy enters into a group of dystrophies with which it has in common their development in growing children and their pathogenesis, symptomatology, anatomopathologic picture, x-ray appearance and clinical evolution. The disease is more frequent than is believed. Some cases are not reported to physicians but improve by

rest or by limitation of physical activities. Others are erroneously diagnosed as achillodynia, talalgia or rheumatism. The disease develops at the time of appearance of the secondary nucleus of ossification of the calcaneus and complete ossification of the nucleus. Circulatory and endocrine disturbances and toxic, dyscrasic and infectious factors, associated with a mechanical stimulation, either unique and strong or continuous and weak, cause subchondral necrosis of the spongy epiphysis with consequent pain in the bone and impaired function of the foot. The early lesion constitutes the place of diminished resistance at which the osteogenic activity is intensified and the blood supply increased. Arrival of bacteria in the primary lesion may cause infectious acute apophysitis, either benign and similar to juvenile dystrophy or grave and even fatal phlegmonosis. The diagnosis is easy because of the fact that the disease has the following clinical characters: It appears in the juvenile age, the pain is located at the point of insertion of the achilles tendon, causes functional incapacity of the foot, has special x-ray aspects in relation to the form and ossification of the bone, and the subjective signs disappear by complete rest of the patient. The differential diagnosis is especially made with tuberculous and pyogenic apophysitis and retrocalcaneal bursitis. As a rule there are no complications. The prognosis is good. The treatment depends on the type and evolution of the disease. It consists in local hot and other applications, rest, use of orthopedic apparatus and a general treatment with phosphorus, iodine, arsenicals, calcium, vitamins and opotherapy. Four cases are reported.

*Powdered Vegetables in Treatment of Anemia in Infants. F. Rubini. p. 33.

Treatment of Rickets. M. Barbone.—p. 40.

Powdered Vegetables in Diet of Infants.—Rubini has examined the blood of a group of twelve infants, ranging in age from 6 to 19 months, who suffered from anemia of varying intensity, before and after administration of a preparation of powdered vegetables. The group included infants fed on mother's milk as well as on artificial or mixed diets. The administration of powdered vegetables added to the diet resulted in increasing the hemoglobin and the number of erythrocytes, the globular value and the globular ratio. The leukocyte formula showed only slight modifications, the lymphocytes being slightly increased at the expense of the neutrophils. According to the author, the improvement in the blood crisis depends on the supply of mineral salts and vitamins contained in the powdered vegetable preparation. The treatment is of value in controlling and in preventing anemia in infants.

Pleural Effusion.—Locascio studied the mechanism of production of D'Amato's signs. They were described in *Riforma medica* 51:1503 (Oct.) 1935 and abstracted in *THE JOURNAL* Dec. 28, 1935, page 2190. The signs described consist in the paradoxical displacement of lateral dullness from the upper to the lower segments of the vertebral column and from the vertebral segment to the cardiac area, when the patient changes from the sitting position to the lateral decubitus and lies on the side opposite to that on which the pleural effusion is located. The author shows, by means of photographs, the behavior of paravertebral and paracardiac dullness in several types of pleural effusion. According to the author the results of roentgen examinations of the thorax during the postural changes of the patient showed that the paradoxical lowering of dullness about the vertebral column is an indication that pleural effusion can be displaced in the pleural cavity. The phenomenon takes place regardless of the presence of intrapleural adhesions if the

effusion is in relation with the vertebral column. The pleural fluid in the posterior costomediastinal sinus advances to upper segments of the vertebral column in the lateral position of the patient. The increased resonance of the segment in relation to that of the patient in the sitting position is due to the fact that, in the lateral position, the pressure of the effusion rests on the mediastinal septum and not on the lung. The dullness of the anterior costomediastinal sinus may not appear in cases of posterior encysted pleurisy. The pleural fluid passes from the posterior into the anterior costomediastinal sinuses during the postural changes. The results were confirmed by exploratory puncture of the sinuses during the postural changes. The author believes that the passage of the fluid in the costomediastinal sinuses is due to physical conditions of the lung, topographic conditions of the organ in relation to the anterior costomediastinal sinus, diminished pressure of the pathologic lung by the gravitational displacement of the heart during the postural change, and changes in pressure of the fluid from pressure on the lung to pressure on the mediastinal septum.

Emotions: Etiologic Role in Heart Diseases. R. Chaminad.—p. 324.

Short Distance Roentgen Treatment of Cancer.—Roffo and Del Giudice administered roentgen irradiations from a short distance, using a tube of the Chaoul type to a group of patients suffering from advanced carcinoma or sarcoma. The focal distance varied between 3 and 5 cm., the tension was 60 kilovolts and the intensity varied between 3 and 4 milliamperes. When the lesions were extensive they were divided in several fields for irradiation. The patients were given the irradiations in fractional doses of 325 roentgens and received a total dose that varied between 2,380 and 14,730 roentgens. The treatment lasted for two or two and a half months. At what intervals the irradiations were given is not specified by the authors. The results were satisfactory in all cases. The tumors disappeared, the ulcers were healed and there was improvement in the general condition of the patients. The treatment is particularly indicated for cancer of the skin, the mucous membranes, the mouth, the fauces and the female genitalia, in which the x-ray tube can be placed in close contact with the cancerous tissues. Some patients obtained satisfactory results from the treatment in cancer of the larynx (which was irradiated through the skin of the neck), in tumoral metastases of the neck from cancer of the larynx and in cancer of the breast. The authors believe that the results of the treatment are due to the increased amount of roentgens that come in contact with the cancerous tissues because of the proximity of the focus to the lesion, to the effect of soft and short wave irradiations and especially to the action of cathode rays.

*Diarrhea in Malaria. P. A. Sainz.—p. 61.

Syphilis in Surgical Diseases. I. Ferrer.—p. 70.

Crenotherapy: History. V. Santamarina.—p. 83.

Diarrhea in Malaria.—Sainz reports five cases of postprandial diarrhea in adults whose recovery was induced by a combined treatment of atabrine and arsphenamine in small doses, the amount of which is not specified. The author believes that the diarrhea was caused by latent malaria with gastro-intestinal localization. In cases of refractory diarrhea in which syphilis, cancer and parasitic infestation are excluded, the presence of malaria should be sought in the past history of the patient. It is advisable to induce spleen contraction by epinephrine injection or expression of the tonsils (the so-called amygdalin test) to induce passage of malarial parasites into the blood with consequent development of a febrile malarial attack, which gives the clue of the malarial etiology of the gastro-intestinal disturbance.

Acute Pancreatitis.—Mahner reports nineteen cases of acute pancreatitis which he observed and emphasizes a preference for the conservative treatment. Operation was performed in four of the cases because of uncertainty as to the diagnosis. The four patients died. Of the fifteen cases in which conservative treatment was administered six were either complicated by or followed obstruction of the common duct. The high diastase content of the urine of the relatively mild cases, as contrasted with the much lower content of some of the severe cases, suggests that there is no parallelism between the diastase content and the severity of the case. On the other hand, increasing diastase content of the urine is proof of an organic disease of the pancreas. The author believes that the natural defense mechanism is capable of taking care of the secondary infection following the acute pancreatic necrosis and therefore he is opposed to surgical intervention at this stage of the disease as well. Operation on the biliary tracts is indicated when it can be proved that they are the direct cause of pancreatitis; the author, however, warns against its performance too soon after the subsidence of acute pancreatitis. The operative intervention may, as in one of his cases, prove to be more dangerous to the pancreatitis than the gallstone disease. He suggests an interval of three months during which the patient is to be carefully supervised and kept on a strictly fat-free diet. Wohlgemuth's determination of the diastase content of the urine is of great diagnostic value in acute pancreatitis. For the cases of somewhat longer duration the Rona and Michaelis serum lipase reaction is of value. The conservative treatment consisted in preliminary fasting days, as advised by Gustav von Bergmann, permitting lightly sugared tea, followed by a fat-free carbohydrate diet.

Malignant Tumors of the Oral Cavity.—Schinz and Zuppinger review the results obtained at the Roentgenologic Institute of the University of Zurich in the treatment of malignant tumors of the epipharynx, mesopharynx, hypopharynx and larynx. For tumors in this localization the authors consider protracted fractional distance irradiation the method of choice. Surgical treatment alone is no longer permissible with the exception of the case of laryngeal fissure in small cancers of the vocal cords. The close range treatment, in the form of radium implantation or the intra-oral radium pack, is to be considered only in tumors of the soft palate uncomplicated by metastases. Electrocoagulation in later combination with radium implantation is utilized as an aid in the treatment of small residual tumors or recurrences of small size. Regional lymph nodes are treated by irradiation. Primary surgical removal is not practiced. The principal advantage of the distance irradiation carried out in the form of prolonged fractional treatment is the complete absence of deforming effect. Of the 115 cases treated, fifty-one were tumors of the movable portion of the tongue, thirty-one of the floor of the mouth, eleven of the buccal mucosa, thirteen of the alveolar process and gum, five of the hard palate and four extensive ones of the oral cavity whose origin could no longer be determined. Hornified flat cell carcinomas predominated. Other types were occasionally seen in tumors involving the hard palate. The authors consider radium implantation in the primary tumor and later removal of the lymph nodes, followed by irradiation, the method of choice in carcinoma of the movable portion of the tongue. Protracted fractional distance irradiation alone, with a later radium implantation in the remnant of the tumor, was employed in the advanced stages of the disease. For small tumors of the floor of the mouth the authors recommend, besides radium implantation, the use of a radium pack and protracted fractional distance irradiation for the advanced stage. The same treatment is applicable to the carcinomas of the buccal mucosa. The treatment of the tumors of the hard palate depends to a great extent on the histologic character of the growth. More or less roentgen resistant tumors, such as gland carcinomas,

should be operated on. Protracted fractional distance irradiation is the only method to be considered in the treatment of diffuse tumors of the oral cavity. More than half of their cases presented an advanced stage of the disease with extensive growth and frequently with regional metastases. Thirty-nine cases of oral neoplasm were treated between 1919 and 1928, but in only twenty was the treatment completed. Seven of the patients were alive one year later, five after three years and five after five years. Of the last five patients only one was treated exclusively by surgery. During the period 1929-1935, seventy-six patients were treated. In sixty-one the treatment was completed. Of forty, thirteen survived a period of three years, and of sixteen, two survived a period of five years. The relative three and five year symptom-free period for the group treated between 1919 and 1928 amounted to 25 per cent. The completely free three year period for the group treated between 1929 and 1933 amounted to 32 per cent, and the relatively free to 40 per cent. The results obtained with primary irradiation followed by later surgical interventions were better than those obtained by primary operation and later irradiation. Two patients out of thirty-two were symptom free after a three year period under the latter treatment, while with the former sixteen out of forty-nine were symptom free at the end of three years. The protracted fractional distance irradiation is capable of giving permanent results with extensive tumors of the oral cavity. Of twenty-two cases of carcinoma of the buccal mucosa, seven were symptom free for from one to four years.

Traumatic Etiology of Acute Yellow Atrophy of Liver.

—Peter shows that from the etiologic point of view acute yellow atrophy of the liver is a complicated process, with the cumulative effect of several factors. It appears that the condition of the hepatic cells is even more important than the type and mode of action of the eliciting factor. Trauma is one of the many factors that may play a part in the pathogenesis of acute yellow atrophy of the liver. The author demonstrates this in a case from the literature and in a case of his own observation. The latter case concerned a man, aged 67. During a fall, the patient's abdomen had been forced against the edge of a wooden box. No definite diagnosis was reached on the basis of the clinical aspects, but acute yellow atrophy of the liver was taken into consideration. The patient died and the necropsy corroborated the existence of an acute yellow atrophy of the liver. In the concluding evaluation the author expresses the opinion that, even in the cases in which the acute yellow atrophy of the liver has a causal connection with a trauma, the condition of the hepatic cells plays a part. The trauma sensitizes the hepatic cells for substances that previously had only a latent toxicity.

Determination of Length of Child in Uterus.—Wegrad

shows that only the measurement of the vertebral column, more specifically the part extending between the first cervical and the fifth sacral vertebrae, is suitable for this purpose. However, to compute the total length of the child it was necessary to determine a definite ratio between the total length of the child and the distance between the first cervical and the fifth sacral vertebrae. This the author did by measurements on a large number of new-born infants. He found that the ratio averaged about 2.29, the use of which can reveal in the individual only

an approximate result. The focus-screen distance is 125 cm. Before the exposure is made, the diameter of the prone woman is measured at the level of the central ray. The length of the vertebral column (between the two points) is measured on the x-ray film and the true length is computed according to the following ratio: true length is to film length as focus-screen distance minus half the diameter of the woman is to focus-screen distance. The resulting figure multiplied by 2.29 gives the total length of the fetus. The author discusses the possible sources of error. The correctness of the method can be determined only if delivery takes place within the first three days after the roentgen examination. Control measurements on fifty new-born infants revealed that in 84 per cent the difference between computed length and actual length was less than 1 cm.

*Deallergization in Hay Fever by Means of Papainized and Peptonized Grass Seeds. E. Urbach.—p. 252.

Clinical Recognition of Hemorrhages Caused by Excessive Production of Estrogenic Hormone. R. Joachimovits.—p. 257.

Deallergization in Hay Fever.—Urbach calls attention to the shortcomings of desensitization of hay fever patients by injections of pollen proteins and then describes a new method. Studies on animals and on human subjects proved that it is possible to improve or counteract hay fever by the oral administration of seed proteins that have been treated with papain or peptone. Preparations of seed proteins containing the proteins of several types of grasses are designated as "polysemims." Several different types of such polysemims have been prepared. For the treatment of hay fever patients who are sensitive to the pollens of various cereals such as rye, wheat or maize, "frumins" were prepared from the brans of these cereals, and "florins" were prepared from the flowers of certain trees for those sensitive to the pollens of these trees. The determination of the types of pollens that cause the hay fever in the individual case is likewise done differently. Whereas formerly it was done by cutaneous or intracutaneous tests, it is now done by the nasal pollen test. Since the aforementioned protein preparations are active only in the fasting stomach, the author recommends that the tablets be given four times daily: one hour before breakfast, one hour before the noon meal, one hour before the evening meal and again at 11 o'clock at night. If the patient is sensitive to grass, cereal and tree pollens, polysemims, frumins and florins are given. Since the sensitivity to grass pollens is usually predominating, the author recommends three tablets of the polysemims at each medication, but only two tablets each of the other two preparations. The tablets are given pulverized in water, to which either the juice of half a lemon is added or from 1 to 2 teaspoonfuls of an acid mixture consisting of 25 Gm. each of concentrated hydrochloric acid and of dry pepsin with distilled water to make 200 Gm. Patients with hyperacidity do not tolerate the acid mixture and are given the protein preparations alone. The author stresses the following as the advantages of this treatment: the oral medication, harmlessness, painlessness, elimination of the time-consuming preseasonal treatment and possibility to effect a deallergization by a systematic treatment of three or four weeks' duration.

Chronic Articular Diseases Treated with Fluorine Salts.—Jankowski reviews the literature on the use of fluorine salts in the treatment of chronic articular diseases and describes seventeen cases which he has treated and in which he has observed beneficial results. After all known methods

of therapy had been exhausted without obtaining any benefit, he tried a 1 per cent watery solution of sodium fluoride. At first he administered orally 5 drops twice a day and then increased the dosage to 10 drops and later to 20 drops three times a day. He found that these doses may be given for months without fear of injury. In some patients the treatment was interrupted for a few days on account of gastric irritation, weakness or vertigo. All cases were notably improved, but it is too early to foretell final results. The calcium level of the blood was studied in four cases and was observed to remain unchanged.

*Ligation of Pulmonary Veins as Method of Hyperemic Treatment of Pulmonary Tuberculosis. L. K. Bogush.—p. 59.

*Velocity of Circulation in Tuberculous Patients. F. V. Shebanov.—p. 86.

Ligation of Pulmonary Veins in Pulmonary Tuberculosis.—On the basis of eleven ligations of pulmonary veins, Bogush concludes that access to the root of the lung and ligation of the vein is technically quite feasible after resection of the cartilage and of a portion of the third rib. The operation does not present great technical difficulties. He emphasizes at the same time that the ligation of a thick short venous trunk intimately connected with the pericardium, the narrow operative field, the presence of scars and adhesions about the root, the cough reflex whenever the bronchus is compressed and the cardiac pulsations call for delicate manipulations. Complete ligation of the pulmonary vein in tuberculous patients does not produce serious alterations of any kind. In the presence of limited involvement there is noted, in the first days and months after the ligation, a lowering of the temperature, diminution of the cough and of the amount of the sputum, improvement in the general condition and appetite, marked diminution of the catarrhal signs and decrease or disappearance of tubercle bacilli from the expectorations. The author concludes that pulmonary vein ligation is a justifiable surgical intervention in the presence of fresh lesions limited to one lobe and not marked by great destruction. In the presence of an extensive destructive process with copious expectoration and high temperature, vein ligation may be useful as a preliminary procedure to the operation of thoracoplasty in order to reduce the secretion, lower the patient's temperature and improve the general status.

Velocity of Circulation in Tuberculous Patients.—Shebanov utilized the method of injecting 1 cc. of a 10 per cent solution of calcium chloride in the cubital vein to determine the speed of circulation. He performed 300 tests in 120 patients exhibiting a variety of types of pulmonary tuberculosis and subjected to various therapeutic regimens. The average speed, as measured by the time elapsed between the injection and the point at which the patient experiences a burning sensation at the root of the tongue, amounted to 12.7 seconds. According to the author, changes in the velocity depend on the toxic action on the circulatory system and on the mechanical alterations following active surgical interventions. These alterations constitute an objective criterium as to the permissibility or the limit of such interventions. A pronounced toxemia causes slowing of the circulation by depressing the cardiovascular system. Artificial pneumothorax increases the velocity of circulation by diminishing the toxemia and the territory of the lesser circulation. Functional adaptability of the circulatory organs determines the limit of acceleration of the blood stream. A sharp change from acceleration to slowing of the blood stream signifies an untoward effect of gas insufflation on the circulatory function. Too great acceleration does not guarantee sufficient aeration of the blood and does not remove anoxemia. Phrenico-exeresis accelerates the blood stream in the presence of fresh lesions and in the absence of a prolonged toxic depression of the heart. However, in the presence of functional cardiac insufficiency phrenico-exeresis may lead to further slowing of the blood stream. Determination of the blood stream velocity made before a thoracoplasty or between different stages of operations enables one to detect a latent

insufficiency of the cardiovascular apparatus and to forewarn against the risk of the operation. Pleurisy with a serous, and particularly with a purulent, exudate slows the circulation as a result of toxemia. Determination of the velocity can be used as an index to the proper time for evacuation of the exudate. The calcium method of determination of the velocity of circulation is useful as an index of prognostic significance as well as an index of therapeutic measures.

Thrombopenic Purpura After Treatment with Arsphenamine, with Recovery After Blood Transfusion: Case. A. Stigaard.—p. 138.

Immunization Against Diphtheria with Purified Anatoxin in Iceland.—Dungal says that diphtheria, which was unnoticed in Reykjavik for eight years, suddenly began to appear early in 1935. Since the Schick tests showed extensive susceptibility, immunization with anatoxin was carried out in 65.5 per cent of the population up to 13 years of age. The antigens used were Ramon's anatoxin and, in most cases, purified anatoxin (Schmidt) with aluminum hydroxide. The latter gave better results, with local reaction in 36.8 per cent and rise in temperature in 39.6 per cent. The immunization percentage was lower than in other countries, presumably because the stimuli of latent infection were lacking.

*Treatment of Arterial Hypertension with Rhodan. K. H. Fremming.—p. 162.

Bradycardia in Young Man: Case. E. Rud.—p. 167.

Treatment of Arterial Hypertension with Rhodan.—Fremming reports that twenty-two patients, all with systolic blood pressure of more than 200 mm., were ambulant treated with potassium and sodium rhodan. A reduction of more than 60 mm. in systolic blood pressure resulted in three, of between 40 and 60 mm. in fifteen and of between 20 and 40 mm. in four. The average decrease was 49 mm. in the systolic and 20 mm. in the diastolic blood pressure. Six of the patients were completely relieved of symptoms, ten noted a definite improvement, and in six the condition was practically unchanged. During treatment the rhodan content of the serum was controlled by a photometric method devised for this purpose, and the dosage adapted accordingly. The optimal rhodan concentration in the serum during treatment was from 7 to 12 mg. per hundred cubic centimeters. The dosage required for this concentration varied individually from 0.15 to 0.5 Gm. daily. No grave complications were seen during the treatment.

*Review of Bactericidal Substances in Normal Blood Especially in Man, Together with Investigations on Thermostable Bactericidal Substance, Particularly Occurring in Serum of Fever Patients: Preliminary Report. P. Hjorth.—p. 192.

Bactericidal Substances in Normal Blood.—Hjorth discusses the thermolabile alexin, the thermostable B-lysin and the bactericidal leukocyte substances (leukins or endolysins), and the thermostable bactericidal substance discovered by Wulff, especially to be found in serum from fever patients. In his personal investigations he found twenty-eight out of thirty strains of meningococci sensitive to the substance, also four apathogenic, gram-negative cocci and a Staphylococcus albus strain. Investigations in series in patients with fever showed that the thermostable bactericidal substance appears a few days after the fever sets in and does not disappear until the temperature has been normal for a few days. This property in the fever serum disappears only on heating to 68 C. for half an hour. A serum thus inactivated can be reactivated by the addition of small quantities, in themselves inactive, of active serum or of serum heated to 56 C. for half an hour. So far its effect has been studied only in meningococci. The author is inclined to class the substance in question with the B-lysin group.

LESIONS OF "ENCEPHALOMYELITIS" AND MULTIPLE SCLEROSIS

VENOUS THROMBOSIS AS THE PRIMARY
ALTERATION

TRACY J. PUTNAM, M.D.
BOSTON

The experimental production in animals of venular thrombi scattered throughout the body has been reported by Flexner,¹ Kusama² and others following the administration of a great variety of substances. These include homologous and heterologous serum, organ extracts, bacterial filtrates, bacterial suspensions, colloidal materials, fat solvents, and salts of some heavy metals. The thrombi are of various types, some consisting chiefly of agglutinated platelets, others chiefly of stromas, others of strands of fibrin or amorphous material. Evidence has been submitted by Kusama² to show that these thrombi may redissolve in the course of time without becoming organized. Hoefer,³ working at the Neurological Unit, is in the process of repeating the fundamental observations and finds that of the various fractions of heterologous plasma the globulin (fig. 1), and that of the various organ extracts lung extract of Mills⁴ is perhaps the most potent. Campbell and Alexander⁵ have produced amorphous capillary and venular thrombi in the brain in experimental local anaphylaxis.

Similar thrombi in both fresh and advanced stages are frequently observed in human pathologic studies, although surprisingly little attention has been paid to them. I have been unable to find any systematic study of them, although they are familiar to every pathologist. They constitute a problem which is entirely different from that of thrombosis in large vessels, such as the heart or aorta, since the flow of blood stops entirely in the venule or capillary once the clot forms. They are therefore apt to lead to necrosis of the vessel wall rather than to organization and recanalization.

Venular thrombi occur particularly in the course of infectious diseases (fig. 2) and indeed are such a commonplace finding that they often escape comment. They have been more thoroughly studied in connection

with certain types of nephritis⁶ and appear to provoke a chronic inflammatory reaction in the kidney. They have also been reported in late death after carbon monoxide poisoning,⁷ and I have found them in a case of nitrous oxide poisoning.

Little attention has been paid to the occurrence of such thrombi in the brain, although it might well be expected that more serious damage should be produced by vascular obstruction there than in any other organ. In the earlier experimental work convulsions, coma and paralyzes were regularly reported, but no histologic examination of the nervous system was given. Thrombosis of veins of the white matter, producing demyelination, was reported by Meyer⁷ and others in a carbon monoxide poisoning. Hoefer's³ and Campbell and Alexander's⁵ experiments were directed toward a study of the cerebral lesions, and they show that clots are as easily provoked in the central nervous system as in any other organ. Indeed, there is some reason to believe that the tortuosity of the cerebral veins and the slowness of the flow within them predispose them to thrombosis.

THE RESULTS OF VENOUS OBSTRUCTION IN THE BRAIN

The effects of venous obstruction in the central nervous system have been studied experimentally⁸ and pathologically in this laboratory. The two sets of observations lead to the same conclusions. The stasis affects the white matter more than the gray. The commonest lesion consists of a swelling and disintegration of myelin upstream along the vein (fig. 3), accompanied in the severer lesions by some swelling and fragmentation of axis cylinders. There is a diffuse proliferation of astrocytes in the vicinity (fig. 4). At a later stage, phagocytes containing products of parenchymal destruction accumulate within the adventitial sheaths of vessels. Occasionally cells resembling lymphocytes are found.

This histologic picture, characterized by the predominance of acute exudative phenomena, changes gradually to one in which cellular activity is almost at a standstill. At most a few phagocytes are found within hypertrophied adventitial meshes. The axis cylinders resume a more normal appearance, and it often becomes difficult to be sure that any are missing. The destroyed myelin is apparently never regenerated, and the rough, indistinct edges of the area of myelin loss gradually become smooth and distinct. The glial fibrosis continues to grow more dense at least up to a year after the insult has occurred.

THE LESIONS OF VENOUS THROMBOSIS AND
THOSE OF "ENCEPHALITIS"

Neuropathologists will recognize at once that the acute lesion which has been described corresponds in all its details with that which is considered characteristic of certain types of "encephalomyelitis"; for example, the postvaccinal and postmeasles forms.⁹ In these con-

Fig. 1.—Clot in a cerebral venule of a rabbit that died forty minutes after the intravenous injection of lung extract. The clot consists of red cells caught in a dense network of curved strands of fibrin. Mallory's connective tissue stain, low power.

ditions congestion and thrombosis are almost regularly observed (figs. 5 and 6).¹⁰ Thrombi were present in other organs also in the only case of this type in which I have been able to study them (fig. 2).

Fig. 2.—Thrombus from the liver of a patient dying from an "encephalitis" following tonsillitis. Arrows indicate invasion by endothelial cells. Mallory's connective tissue stain, low power.

The possibility that postinfectious "encephalomyelitis" is an allergic phenomenon has been suggested by Glanzmann,¹¹ van Bogaert¹² and others. The onset of the cerebral symptoms coincides with the development of immunity in a striking manner. The relation of allergy to thrombosis and of thrombosis to the cerebral

changes places the entire sequence in a clearer light. It also becomes easier to understand why these "encephalitis" occasionally occur in a hemorrhagic form and how they are related to the cerebral lesions produced by toxic substances such as arsphenamine, carbon monoxide and nitrous oxide.

THE RELATION OF VENOUS THROMBOSIS TO
MULTIPLE SCLEROSIS

It has long since been pointed out that lesions closely resembling those of the postinfectious "encephalomyelitis" may occur in the course of multiple sclerosis, and a careful comparison of various aspects of the two

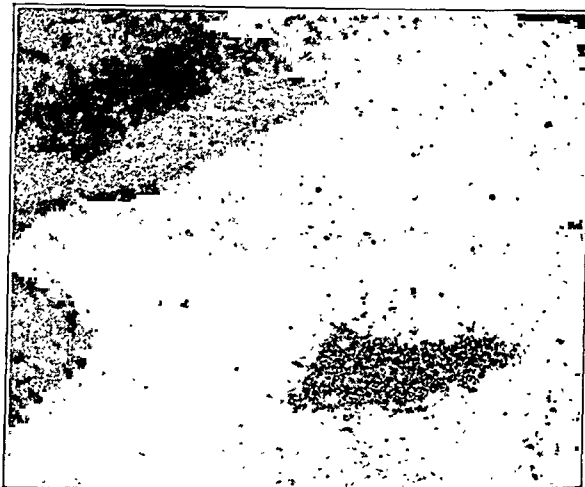

Fig. 3.—Local destruction of myelin fourteen days after experimental obstruction of cerebral venules in a dog. Mallory's connective tissue stain, low power.

groups shows that no sharp dividing line can be drawn between them.¹³ In both conditions, myelin is more damaged than the axis cylinders and can never regenerate in the central nervous system. The axis cylinders are injured or sometimes entirely destroyed in both dis-

eases. The intensity of destruction of axis cylinders is greater the more severe and abrupt is the onset of the lesion, and it is therefore usually greater in fatal

cases of "encephalitis" than in some of the mild, chronic lesions of multiple sclerosis. In the majority of sclerotic plaques, however, many axis cylinders are destroyed.¹⁴ A diffuse glial reaction occurs in areas of fresh degeneration in cases of multiple sclerosis, which is entirely comparable to that seen in "encephalomyelitis." At a later stage in both diseases phagocytic cells of various types accumulate about vessels and later still disappear. The glial scarring that gives multiple sclerosis its name is a slow, chronic process which takes place in much the same way in practically all diseases accompanied by loss of myelin; for example, old arteriosclerotic lesions¹⁵ or secondary degeneration.¹⁴ The typical sclerotic plaque is to be regarded, therefore, as a late stage of the lesion of a certain type of "encephalomyelitis."

The theory of the vascular origin of the lesions of multiple sclerosis has recently received support from two unexpected sources. In the first place, Alexander

sent phagocytized blood pigment rather than fragments of spirochetes, as suggested by Steiner.

This point of view is entirely consistent with the intermittent course of remissions and exacerbations

Fig. 5.—Thrombus in a cerebral vein from a case of postvaccinal "encephalitis." Masses of fibrin enclose red cells. Mallory's connective tissue stain, low power. Compare with figure 1.

and Myerson¹⁶ have shown by means of micro-incineration that a local demineralization is a characteristic feature both of anemic foci and of sclerotic plaques, in sharp contrast to the hypermineralization of inflammatory lesions.

In the second place, Blackman¹⁷ has recently repeated Steiner's work¹⁸ on the occurrence of certain cells which take a specific impregnation with silver in multiple sclerosis and dementia paralytica. Blackman finds that these typical cells occur also in areas of cerebral thrombosis, if the patient has survived a week or more (fig. 7). It appears, therefore, that they repre-

per cent; febrile diseases, 4.2 per cent; overexertion, 3.9 per cent; chilling, 2.3 per cent; fright and emotion, 7.0 per cent, and poisoning, 0.5 per cent.

It is striking that these factors are exactly those which predispose to disturbances of the stability of the blood plasma and to thrombosis.²⁰ Simon and Solomon²¹ have shown that the blood of patients with multiple

Fig. 8.—Typical distorted vessel surrounded by a ring of congested capillaries from an old plaque of multiple sclerosis. From a brain the blood vessels of which were injected with india ink after removal from the skull. Low power.

sclerosis shows an abnormal tendency to coagulation following the administration of adrenal extract or of typhoid vaccine.

Thrombi are found less often in cases of multiple sclerosis than in cases of "encephalomyelitis," doubtless because most of the lesions are older; but they could be demonstrated in five of fourteen cases.²² Other

Fig. 9.—Multiple sclerosis. A necrotic vein, devoid of lumen in this and adjacent sections, lies in a zone of demyelination. A congested vein is seen in the upper left corner. Masson stain, high power.

evidences of vascular obstruction, such as perivascular accumulation of blood pigment and engorgement and tortuosity of vessels, are common, however (figs. 8

and 9). Thrombi also occur in other organs in cases of multiple sclerosis, usually without causing lesions.²² Further reasons have been given elsewhere for considering that the thrombi are primary to the other changes in the lesion and not secondary.²²

SUMMARY

Many of the factors that may lead to a diffuse thrombosis of small veins throughout the body correspond with the recognized antecedents of certain types of "encephalomyelitis" and the onset or exacerbation of some cases of multiple sclerosis. In both these groups of disease, thrombi and other evidences of vascular occlusion are found in relation to the characteristic lesions and in other organs of the body. These lesions correspond closely to the results of experimental and spontaneous occlusion of veins.

It seems probable, therefore, that the primary alteration in certain types of "encephalomyelitis" and multiple sclerosis is an abnormal lability of the blood plasma, which may be caused to clot in venules of the brain (and other organs) by a variety of exogenous (and probably also endogenous) factors.

MECKEL'S DIVERTICULUM

ASSOCIATED WITH INTUSSUSCEPTION AND ADENOCARCINOMA OF ECTOPIC GASTRIC MUCOSA: REPORT OF CASE

HOWARD K. GRAY, M.D.

AND

JAMES W. KERNOHAN, M.D.

ROCHESTER, MINN.

That there is a persistence of the proximal end of the yolk stalk to form a pouch at its point of union with the intestine in approximately 3 per cent of all individuals has been widely recognized. This pouch is usually referred to as "Meckel's diverticulum" and is a structure of clinical importance because of the rôle it may play in producing intestinal obstruction. Benign ulcerating processes in ectopic gastric mucosa have been described with relative frequency and have been incriminated occasionally as the source of intestinal hemorrhage. The development of malignant lesions in the ectopic gastric mucosa of a Meckel's diverticulum is extremely rare, and for this reason we felt that it was justifiable to report such an incident. So far as we have been able to determine, carcinoma of Meckel's diverticulum has been reported in a limited number of cases. According to Franke,¹ Jores noted a primary carcinoma of the cylindric epithelium of a Meckel's diverticulum and reported this in 1899. Oberndorfer² cited one case in 1907, and other instances of this condition have been noted by Schaetz³ (1925), and by Hertzog and Carlson⁴ (1935).

REPORT OF CASE

A married woman, aged 37, registered at the Mayo Clinic on Nov. 22, 1933, complaining of vague abdominal pains that had been present at intervals since the birth of her first child, six years previously. The pain had occurred in the epigastrium, in the lower part of the abdomen, particularly on the right, and in the lower part of the back. There seemed to be no relationship to any factor in her daily routine, and there had not been any associated nausea or vomiting. The patient had eliminated fried foods from her diet because she thought they

might be deleterious, and not because of qualitative food distress. It was impossible to obtain a satisfactory description of her symptoms. That chronic nervous exhaustion played an important rôle was apparent, but her general appearance strongly suggested organic disease. The systemic history otherwise was essentially negative.

Her father had died from stroke; otherwise the family history was essentially negative. She had been married seven years; her husband was alive and well, as were their three children. The patient's menstrual periods had always been irregular, but there had not been any menorrhagia.

Physical examination revealed a systolic blood pressure of 122 mm. and a diastolic pressure of 80 mm. of mercury. The patient was a well developed, somewhat undernourished woman who weighed 98 pounds (44.5 Kg.). There was nearly complete diastasis recti abdominis. She had been operated on in 1928, at which time an appendectomy, a partial right oophorectomy and freeing of adhesions had been performed. There was slight tenderness over the right costal margin, and tenderness and a small mass (3 by 1.5 cm.) were noted in the right lower quadrant of the abdomen. The uterus was moderately enlarged and nodular and had pushed the cervix backward. There was an egg-shaped mass about 5 cm. in diameter in the ileocecal region.

Analysis of a passed urine specimen revealed a specific gravity of 1.036, an acid reaction, a moderate amount of albumin, hematuria grade 4 (the patient was menstruating) and only a slight amount of pus. The value for the hemoglobin was 12.6 Gm. for each 100 cc. of blood. The erythrocytes numbered 3,910,000 and the leukocytes 5,400 per cubic millimeter of blood. The Wassermann reaction on the blood serum was negative. The sedimentation rate was 4.5 mm. in half an hour, 14 mm. in one hour and 40 mm. in two hours. Roentgenologic examination of the thorax, stomach, kidneys, ureters and bladder did not reveal any abnormality. There was some deformity of the coccyx. Roentgenologic examination showed that the gallbladder was functioning normally. A roentgenogram of the colon revealed a filling defect involving the ileocecal region at a point that coincided with the position of the palpable mass. The roentgenologist made the note that the changes suggested an extraluminal mass.

Operation was performed Dec. 4, 1933. Exposure through a low midline incision revealed an intussusception of the terminal portion of the ileum, about 14 to 16 inches (35 to 40 cm.) above the ileocecal juncture. The ileocecal region was essentially normal. A portion of bowel that had become invaginated for approximately 8 cm. was easily reduced. When this was accomplished, it was seen that a second intussusception had

occurred in a portion of tissue, which appeared to be a large Meckel's diverticulum. The diverticulum extended at right angles to the wall of the ileum for approximately 5 cm.; it was 2.5 cm. in diameter at the base and about 5 cm. long. At the tip, a portion of the mesentery of the diverticulum had become intussuscepted into the bowel. It was impossible to reduce this, and a segmental resection of the ileum was performed by making an end-to-end anastomosis. In order to insure an adequate lumen of the bowel, an entero-anastomosis was made about 8 inches (20 cm.) from the end-to-end anastomosis. Pelvic examination revealed that the right ovary was somewhat small but otherwise normal. The left ovary was slightly cystic. The uterus was apparently normal. The upper portion of the abdomen was not explored.

The convalescence following this procedure was uneventful, and the patient was able to leave the hospital on the sixteenth postoperative day. Final surgical dismissal was granted on the nineteenth postoperative day. At this time the wound had healed and the general condition of the patient was good.

A letter received from the patient a year later stated that she had not had any severe pain in the region of the operative wound but that she had "a slight discomfort in the right side at times."

Examination of the tissue removed at operation revealed about 3 cm. of ileum. Arising from the middle of this was a Meckel's diverticulum which was 5 cm. long. This had a prominent mesentery, which had become herniated into the ileum along with the inverted diverticulum. The specimen was opened and a fungus-like mass was found to occupy the distal third of the diverticulum (fig. 1), while the middle third had a peculiar granular or cobblestone appearance similar to that which is frequently seen in the wall of the stomach. The proximal third was lined by mucosa of normal ileum. The tissue had been fixed in 10 per cent solution of formaldehyde, and histologic preparations were subsequently made and stained with hematoxylin and eosin and also with the mucicarmine method for mucus.

The mucosa of the ileum and the proximal third of the diverticulum was normal. At the base of most of the glands there were typical Paneth cells with their eosinophil granules. The stroma was edematous and contained some lymphocytes. The muscularis mucosae and the muscle layers were intact and

Fig. 1.—Meckel's diverticulum; proximal third is composed of normal ileal mucosa, middle third consists of gastric mucosa (one may note the "cobblestone" appearance) and the distal third is the site of an ulcerating carcinoma on which an exudate may be seen.

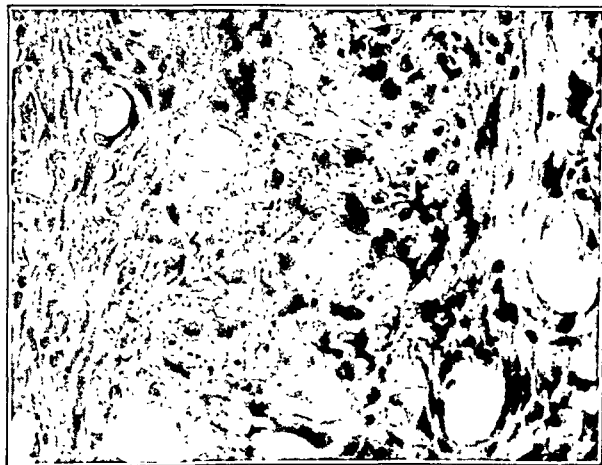

Fig. 2.—Adenocarcinoma involving surrounding tissues; specimen stained with hematoxylin and eosin; slightly reduced from a photomicrograph with a magnification of 350 diameters.

normal except for the presence of slight edema. In the mucosa at the junction of the proximal and middle thirds there was a marked change in the character of the glands and epithelium. The glands were less simple; epithelial cells that contained mucus were not present and there were no Paneth cells. The microscopic appearance was typical of gastric mucosa, except that there were no parietal cells and there was a chronic diffuse inflammation throughout the mucosa. This inflammation was limited to the stroma, while the epithelium of many of the glands was hyperplastic and the glands themselves were irreg-

ular, dilated and tortuous. The muscularis mucosae and the muscular walls of the diverticulum were normal. The histologic appearance of the middle third of the diverticulum was similar to the portion just described. The mucosa was identical to gastric mucosa in which there is an advanced, diffuse, chronic gastritis. Where the inflammation did not directly affect the epithelial cells they were hyperplastic and mitotic figures were common. The entire epithelium was intact and no ulceration was present. The mucosa of the distal third of the diverticulum was much thicker than that of the middle third, and the super-

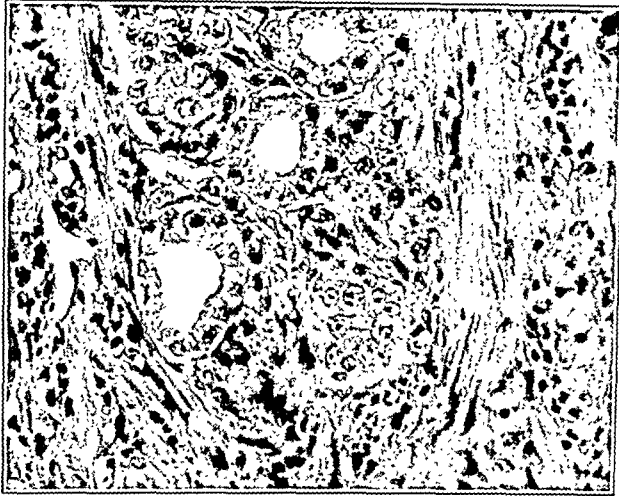

Fig. 3.—Adenocarcinoma, grade 2, invading the muscle of the diverticulum; specimen stained with hematoxylin and eosin; slightly reduced from a photomicrograph with a magnification of 325 diameters.

ficial portion was ulcerated and covered with a layer of fibrin that contained polymorphonuclear cells. The underlying epithelium was very hyperplastic; the nuclei were large and contained prominent nucleoli. Mitotic figures were numerous (fig. 2). In some regions the cells were arranged in the form of glands, which were irregular, tortuous or dilated (fig. 3), while in most places no definite glandular arrangement of the cells was present. The cells were scattered diffusely throughout the stroma and in many places they had grown through the muscularis mucosae. In a few places they had extended down to, and in one or two places they had actually invaded, the muscular wall of the diverticulum (fig. 3). They had not penetrated to the peritoneum. Along with the downgrowth of the epithelium there was a chronic inflammation extending from the ulcerated surface of an adenocarcinoma (fig. 4). The carcinoma was identical with slowly growing adenocarcinomas of the stomach. The entire middle third of the diverticulum consisted of chronically inflamed heterotopic gastric mucosa. This portion gradually merged into the distal third, which was the site of an adenocarcinoma. (We are unaware of any case described in the literature in which an annular heterotopic gastric tissue occupied the middle third of the diverticulum while the proximal and distal thirds were composed of iliac mucosa.) Moreover, there was a gradual transition between the heterotopic gastric mucosa and the carcinoma at the tip. In stomachs in which carcinoma is present there is usually a chronic diffuse gastritis associated with a marked hyperplasia of the gastric mucosa. The histologic observations in this case were identical with those usually occurring in cases of carcinoma of the stomach.

COMMENT

Heterotopic gastro-intestinal tissue has often been found in Meckel's diverticula. Frequently, heterotopic gastric mucosa has become ulcerated and has produced hemorrhages, and perforation occasionally has resulted and has led to fatal peritonitis. This subject has recently been the basis of an excellent review by Schullinger and Stout,⁵ who also describe an adenoma

of Meckel's diverticulum that was composed of gastric and duodenal mucosa. This adenoma was not malignant.

Carcinoid tumors occasionally have been found in Meckel's diverticula and there are numerous reviews of these in the literature. We have had an opportunity to examine two such tumors, which have been described by Hertzog and Carlson of the clinic. The gross and microscopic appearance of these small tumors is characteristic. They are found most commonly in the appendix and small intestine. Several that have been observed have become malignant and have metastasized to the mesenteric lymph nodes and liver. However, the metastatic tumors retain most of the characteristics of the original growth and are readily distinguished from most other types of carcinoma.

The case we have described seems to us to be unique in that the diverticulum was removed while the carcinoma was sufficiently small to allow us to observe the origin of the carcinoma from the heterotopic gastric mucosa. The portion of the heterotopic tissue that had not been replaced by carcinoma was typical of gastric mucosa. There was chronic diffuse inflammation throughout the mucosa and the epithelium was hyperplastic, while the glands were tortuous and irregular. The hyperplastic appearance suggested a precancerous condition, which is often seen in cases of chronic gastritis.

A survey of the literature on neoplasms of Meckel's diverticula reveals that most tumors are carcinoid tumors, although several sarcomas of various types have been observed. A few adenocarcinomas have been reported. Wiseley⁶ (in 1931) found an adenocarcinoma of Meckel's diverticulum while exploring the abdomen prior to the repair of a hernia. The wall of the diverticulum was nodular and thickened down to

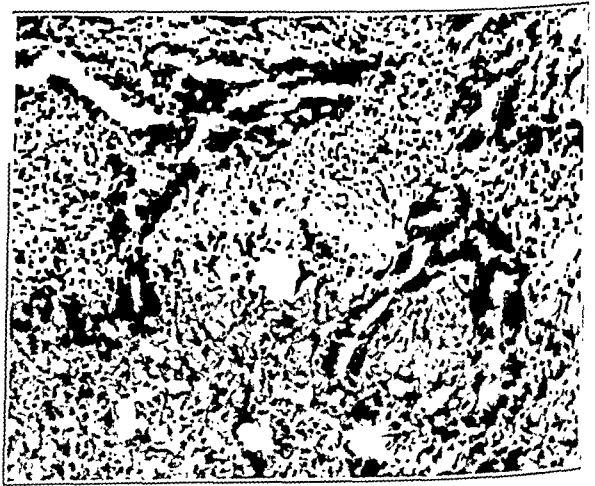

Fig. 4.—Adenocarcinoma in which cells are attempting to form glands, which are irregular and are spreading through the muscularis mucosae; one may note the hyperplastic epithelium. Specimen stained with hematoxylin and eosin; slightly reduced from a photomicrograph with a magnification of 210 diameters.

and including the wall of the small intestine. The involved portion of this intestine was resected. The diagnosis was a medullary carcinoma. No metastasis was found at necropsy. In 1932 Michael and Bell⁷

6. Wiseley, A. N.: Medullary Carcinoma of Meckel's Diverticulum. *J. A. M. A.* 96: 1949-1950 (June 6) 1931.

7. Michael, Paul, and Bell, H. G.: Primary Adenocarcinoma Arising in a Meckel's Diverticulum, *Surg., Gynec. & Obst.* 54: 95-97 (Jan.) 1932.

5. Schullinger, R. N., and Stout, A. P.: Meckel's Diverticulum. *Arch. Surg.* 28: 440-466 (March) 1934.

described an adenocarcinoma of the ileum, which originated in a Meckel's diverticulum. The carcinoma had extended through the muscularis mucosae into the outer wall of the diverticulum and adjacent ileum, and according to the description it appeared to be a highly malignant growth. The patient recovered following a resection and no mention of further extension or metastasis was made. Franke in 1933 reviewed the literature and reported an additional case in which an adenocarcinoma of a Meckel's diverticulum had extended through the intestinal wall and into the peritoneal cavity. Most of the carcinoma was necrotic, but in some places mucus-containing glands were present. There was no mention of metastasis to mesenteric lymph nodes or to the liver. The same year Brown⁸ described a case in which a mass was attached to the ileum. There was no mention of the presence of a Meckel's diverticulum and the description was not typical of an adenocarcinoma, but the tumor could be considered a sarcoma. The tissue was not examined for mucus.

In none of these cases was there any mention of heterotopic tissue in the Meckel's diverticulum; however, it is possible that one or more of these carcinomas arose from preexisting heterotopic tissue and that when the neoplasm had grown to sufficient size to produce symptoms it had completely destroyed the tissue from which it arose.

SUMMARY

In a case of intussusception of the terminal portion of the ileum there was a second intussusception, which was an inverted Meckel's diverticulum. The distal two thirds of the mucosa lining this diverticulum consisted of heterotopic gastric mucosa. Examination of this mucosa revealed chronic inflammation. The distal third of the heterotopic gastric mucosa had been replaced by an adenocarcinoma, grade 2 on a basis of 4. Ulceration and infection of the carcinoma had occurred and the tumor had grown through the muscularis mucosae but had not extended to the peritoneum. The patient recovered and was living one year after removal of the tumor and there was no evidence of metastasis. This was a unique case in that the diverticulum was removed during the early growth of the carcinoma before it had destroyed the heterotopic gastric mucosa from which it arose.

Trust Them Not, Young Man.—But the young doctor, the new doctor, in a gossip house, must never be off his guard. He has seen and prescribed for his patient and has said all that need be said to the friends; and there is tea, and what seems a favorable opportunity for extending the practice. Trust them not, young man: put your fingers in your ears, and flee from the City of Destruction of Reputations. If you must stay, do not stay long, and keep the door of your lips. Talk of the patient, of the weather or of the proposition, which will as surely as the bread and butter be handed to you, that there is a good deal of illness about. Avoid all topics of Church and State, quote neither poetry nor prose, give neither censure nor approval to music and the drama, hide your liking for any art but your own. Leave behind you, for gossip to lap, a saucerful of the milk of human kindness. Never mind about producing a favorable impression; produce this one impression, that you know your work, and that it will not be your fault if the mixture fails to relieve the patient upstairs: and then flee.—Paget, Stephen: *Confessio Medici*, New York, Macmillan Company, 1931.

ANTIPNEUMOCOCCUS RABBIT SERUM AS A THERAPEUTIC AGENT IN LOBAR PNEUMONIA

F. L. HORSFALL JR., M.D.

KENNETH GOODNER, Ph.D.

C. M. MACLEOD, M.D.

AND

A. H. HARRIS 2d, M.D.

NEW YORK

Antipneumococcus serum is at present the only specific therapeutic agent useful in the treatment of lobar pneumonia. The first conclusive evidence of the effectiveness of specific serum in type I pneumococcus pneumonia was brought by studies made in the Hospital of the Rockefeller Institute in 1912-1913.¹ During the twenty-four years since the publication of this report the value of type I antipneumococcus serum has been conclusively proved by studies in this hospital,² and these results have been confirmed and extended by numerous workers.³

In type II pneumococcus pneumonia the value of antipneumococcus serum is somewhat less definite, but the reports of Bullowa,⁴ Cecil and Plummer,⁵ Finland and Sutliff⁶ and Finland and Dowling⁷ indicate that the mortality rate may be reduced by the early administration of adequate amounts of serum.

The results of specific serum therapy in type VII and type VIII pneumococcus pneumonias have been favorable although perhaps not quite as satisfactory as in the case of type I.⁸

Since its introduction, therapeutic type-specific antipneumococcus serums have been produced by immunization of horses. Although, as has been stated, its use has been attended with good results in a number of different types of pneumococcal pneumonia, it has always possessed certain inherent characteristics that have not been entirely desirable. These are:

1. Antipneumococcus horse serums rarely possess high mouse protective titers. On the average raw type I antipneumococcus horse serum contains approximately 500 mouse protective units per cubic centimeter. An occasional animal may produce serums of twice this potency, but this is uncommon. Since the amount of antibody is not great and since large amounts of antibody are necessary for the treatment of pneumonia, it has been useful to employ concentration methods. Because of technical procedures involved, concentration has added materially to the final cost of serum.

2. Intravenous injections of antipneumococcus horse serum occasionally cause anaphylactic or anaphylactoid reactions and,

although these can usually be counteracted by the judicious use of epinephrine, they are objectionable.

3. Chill reactions, as distinguished from anaphylactoid reactions, commonly follow the injection of antipneumococcus horse serum. These are generally not dangerous but they are distressing to the patient. The use of concentrated horse antiserum has considerably decreased the incidence of these chill reactions but, even with concentrated serum, chills are encountered in about 15 per cent of the cases.⁹

4. Serum sickness develops during convalescence in a very high percentage of patients treated with antipneumococcus horse serum. The use of concentrated horse serum has decreased the incidence of serum sickness somewhat, but in a recent paper Abernethy² reported its occurrence in 68 per cent of his cases.

5. It is generally believed that horse antiserum does not reduce the incidence of empyema in pneumonia. Once pleural fluid becomes infected, no amount of horse antiserum will affect the subsequent course of the exudate. In a search of the literature we have been unable to find any evidence indicating that horse serum antibody has been demonstrated in pleural fluid after intravenous injection. Sabin¹⁰ attacked this problem directly and was unable to demonstrate antibody in the pleural fluid from five patients shown to have circulating type-specific antibody.

During a series of studies directed toward the numerous differences between type I antipneumococcus serums of many mammalian species, it became apparent that the use of antipneumococcus rabbit serum might afford a means of circumventing some of the less desirable characteristics of antipneumococcus horse serum. Type I antipneumococcus rabbit serum has been shown to differ in more than thirty distinct immunologic characteristics from type I antipneumococcus horse serum.¹¹

The more significant characteristics of antipneumococcus rabbit serum which have served as a rationale for its trial in the therapy of lobar pneumonia are as follows:

1. Unconcentrated rabbit antiserum has a relatively high mouse protective potency as compared with horse antiserum. Immune rabbit serum contains approximately 200 protective units per milligram of protein specifically precipitable by the homologous pneumococcus capsular polysaccharide, whereas most horse antisera contain only about 90 units.

2. The rabbit antibody is of relatively small size as compared with the horse antibody. From the results of a number of recent investigations, it now appears quite definite that the antibody from horse serum is at least from three to four times larger than the antibody from rabbit serum. This has been demonstrated both by ultrafiltration¹² and by ultracentrifugation.¹³ Other factors being constant, the smaller the antibody the more effective should be the penetration into infected tissues.

3. Protection fails entirely when greater than optimum amounts of horse antiserum are used in the mouse protection test. This prozone phenomenon does not occur with immune rabbit serum.¹⁴

4. The mouse protective action of horse antipneumococcus serum is inhibited by physiologic amounts of cholesterol and cephalin. The addition of these lipids to rabbit antipneumococcus serum does not affect its protective action.¹⁵

5. The immunization of horses is uncertain and slow as compared with the ease and rapidity with which rabbits can be immunized. Not every horse produces serum of useful potency and, in general, immunization requires a period of six months or more. Almost 100 per cent of rabbits produce antiserum of high potency after immunization with type I pneumococci. By intensive immunization it is possible to obtain in as short a

time as four weeks serum containing about 2,000 mouse protective units per cubic centimeter. On the other hand, unconcentrated horse serum averages about 500 units per cubic centimeter. There is reason to believe that, with other types of pneumococci, rabbits are much more readily immunized than are horses.

6. It would seem from the best estimates available that, on the basis of equivalent amounts of protective antibody, unconcentrated rabbit serum costs approximately one fifth as much as concentrated horse serum.

Because of these considerations, unconcentrated type specific rabbit serum has been used in the treatment of lobar pneumonia in the Hospital of the Rockefeller Institute during the past twelve months. A preliminary note as to the reasons for its trial has already appeared.¹⁶ The results obtained in the treatment of twenty-two cases form the subject of this paper.

PREPARATION OF TYPE SPECIFIC RABBIT ANTIPNEUMOCOCCUS SERUMS

Rabbits weighing from 3 to 5 Kg. were immunized by the intravenous injection of suspensions of pneumococci treated with formaldehyde. The precise method of immunization need not be detailed but in general the plan involved intensive courses, frequently repeated, so that high antibody titers would be achieved in a short period of time. Blood was collected with aseptic technique by cardiac puncture, 50 cc. being withdrawn from each rabbit every two weeks. Antibody titers were maintained by additional intravenous injections of pneumococcus suspensions after each bleeding. The serum from rabbits immunized with a single type was pooled and filtered through a Berkefeld V candle. Methylolite to a final concentration of 1:10,000 was added and the serum stored in the icebox until a considerable quantity had been collected. It was then heated to 56 C. for thirty minutes and after cooling was absorbed with washed sterile kaolin. Absorption was carried out for fifteen hours at 4 C., 5 Gm. of kaolin per hundred cubic centimeters of serum being used. After separation of the kaolin by centrifugation the serum was again filtered through a Berkefeld V candle and filled into vials of suitable size. The usual sterility and toxicity tests were carried out.

ADMINISTRATION OF SERUM

Immediately after the patient's admission the diagnosis was confirmed by x-ray examination and the type of pneumococcus in the sputum was determined by the Neufeld reaction. Subsequently the typing was confirmed by mouse inoculation.

Before therapeutic intravenous administration of serum, all patients were tested for sensitivity to rabbit serum in a routine way by three methods:

1. *Intradermal Test.*—One-tenth cubic centimeter of a 1:10 dilution of normal rabbit serum in physiologic solution of sodium chloride was injected intradermally. This was controlled by a corresponding injection of saline solution. All patients have reacted positively. In many this reaction appeared as a small and transient erythematous patch, while in a few cases there developed a blanched wheal with circumferential erythema. It was found that none of these positive reactions were significant as an indication of sensitivity to rabbit serum injected intravenously.

2. *Conjunctival Test.*—One-tenth cubic centimeter of a 1:10 dilution of normal rabbit serum in physiologic solution of sodium chloride was instilled into one conjunctival sac. None of the patients tested showed a positive reaction, as evidenced by injection of the conjunctival vessels, itching or lacrimation.

3. *Intravenous Test.*—One-tenth cubic centimeter of the type-specific antipneumococcus rabbit serum to be used was diluted with 5 cc. of saline solution and injected intravenously. A

positive reaction with this test consists of a fall in arterial blood pressure and an increase in pulse rate within five minutes. No positive reaction has been observed in any case in this series.

Following a negative reaction to the intravenous test the administration of serum was begun. In the first few cases 2 cc. of serum diluted to 20 cc. with saline solution was given initially, and the volume of serum

was then doubled every two hours until from 30 to 40 cc. of undiluted serum was given at each injection. Later it was found that a greater increment could be used and that the administering of serum at intervals of forty minutes produced a more rapid drop in temperature. In the last few cases an attempt has been made to give an adequate therapeutic amount of serum at one injection. No symptoms whatever have followed the intravenous administration of 125 cc. of undiluted serum over a period of ten minutes.

The first therapeutic injections of rabbit serum were not infrequently followed by chill reactions of the delayed type. These reactions occurred from forty-five to sixty-five minutes after administration of the serum. A chill occasionally followed the second and rarely the third injection. After these initial chills a refractory period occurred and chills did not result from additional serum unless it became necessary to change to a different lot. It has been found that heating the serum to 56 C. for thirty minutes and adsorbing with sterile kaolin reduces considerably the amount of the chill producing substances. The simultaneous oral administration of 0.9 Gm. of acetylsalicylic acid with the first injection of serum has prevented practically all chill reactions in the last few cases.

TYPE I PNEUMOCOCCUS PNEUMONIA

Ten patients with type I pneumococcus pneumonia have been treated with unconcentrated type I antipneumococcus rabbit serum. The more important data are summarized in table 1. Eight of the ten patients had bacteremia on admission and one had a pleural exudate grossly infected with type I pneumococcus. Four of the ten patients entered the hospital with consolidation of two or more lobes and two of the four had bilateral consolidation. Two patients were sufficiently ill to necessitate treatment in the oxygen chamber. Pneumonia had been present for an average of forty-two

hours before type I rabbit serum therapy was begun. The administration of serum was carried out over an average period of nineteen hours in the ten cases. The total unconcentrated serum dosage averaged 124 cc. per case, or 248,000 units. The temperature, pulse and respiratory rates came to normal by crisis in an average of twenty-three hours after the institution of serum therapy or sixty-five hours from the beginning of the disease. Skin tests with type I capsular polysaccharide were positive at the time of the critical fall in temperature in seven of the ten patients. In two patients the skin test was equivocal and in one it remained persistently negative. Chill reactions occurred in six of those treated with type I rabbit serum. Recovery occurred in all ten patients and was entirely uneventful in eight. Midopliteal thrombophlebitis developed in one case. In two patients mild serum sickness of the urticarial type occurred ten days after the beginning of serum therapy, and of these one also had slight arthralgia.

One patient (case 1) requires special mention. On admission there was present a turbid pleural exudate which was grossly infected with type I pneumococcus. Following the intravenous administration of type I rabbit serum, type I antibody appeared in the exudate. Subsequently the exudate became sterile and was absorbed. The presence of antibody was demonstrated by agglutinin and precipitin reactions as well as by the mouse protection test. Surgical drainage was not required.

TYPE II PNEUMOCOCCUS PNEUMONIA

Four patients with type II pneumococcus pneumonia have been treated with unconcentrated type II antipneumococcus rabbit serum. The more important data are presented in table 2. Two patients had consolidation of two lobes on admission, in two there were pleural exudates grossly infected with type II pneumococcus, one had type II bacteremia, one auricular fibrillation, and in one delirium tremens developed. Two required treatment in the oxygen chamber. The disease had been present for an average period of seventy-four hours

before serum therapy was begun. The administration of serum was carried out over a period which averaged fifty hours for the four cases. The total unconcentrated serum dosage averaged 231 cc. per case. A drop in temperature, pulse and respiratory rates to normal occurred at an average of forty-two hours after the beginning of serum therapy, or an average of 116 hours after the onset of the disease. Skin tests with type II capsular polysaccharide were positive either at the time or shortly after the defervescence in all four cases. Chill reactions following serum occurred in three of the four patients. Serum sickness of the urticarial type occurred in each of the four patients, but in no instance

was it severe and arthralgia occurred in only one. Three patients recovered.

The two patients who had pleural exudate grossly infected with type II pneumococcus deserve separate mention. In case 2 there was a considerable collection of pleural exudate, which contained large numbers of type II pneumococci. It was not possible to demonstrate the presence of type II antibody in this fluid after

the intravenous administration of type II rabbit serum. Loculated empyema developed and surgical drainage was instituted. This patient died suddenly five weeks after admission following rupture of a dissecting aneurysm of the thoracic aorta. This occurred into the empyema cavity. In case 13, 300 cc. of pleural exudate was withdrawn shortly after admission. This fluid contained large numbers of type II pneumococci. Following serum therapy it was possible to demonstrate the presence of type II antibody in this fluid and to prove immunologically that the antibody was of rabbit origin. Thereafter the exudate became sterile and operation was unnecessary. In the remaining two patients, convalescence was otherwise uneventful and uncomplicated.

TYPE VII PNEUMOCOCCUS PNEUMONIA

Three patients with type VII pneumococcus pneumonia have been treated with unconcentrated type VII antipneumococcus rabbit serum. The pertinent data are shown in table 3. One patient had type VII pneumococcus bacteremia on admission and one marked jaundice. Serum therapy was instituted after an average of thirty-three hours following the onset of the

disease and was continued for an average of fourteen hours. The total unconcentrated serum dosage averaged 145 cc. per case. The temperature, pulse and respiratory rates dropped to normal by crisis in an average of nineteen hours after the beginning of serum therapy, or fifty-three hours after the onset of the disease. All recovered uneventfully. Moderate chill reactions occurred in two patients. In all three mild urticarial serum sickness developed and in one a sterile pleural effusion.

TYPE VIII PNEUMOCOCCUS PNEUMONIA

Five patients with type VIII pneumococcus pneumonia have been treated with unconcentrated type VIII antipneumococcus rabbit serum. The data are presented in table 4. Two patients had type VIII pneumococcus bacteremia on admission, one had bilateral consolidation, one was addicted to the use of dilaudid hydrochloride, and one was so ill as to require oxygen therapy. An average of thirty-eight hours elapsed from the onset of the disease until serum therapy was commenced. This was continued for an average period of eighteen hours. A total of 173 cc. of unconcentrated serum was given per case. The temperature, pulse and respiratory rates reached normal by crisis in an average of twenty-three hours from the institution of serum therapy or an average of sixty-two hours after the onset of the disease. Mild chill reactions occurred in four of the five patients. All five patients recovered. Convalescence was uncomplicated in all cases except for moderate urticarial serum sickness in three.

COMMENT

Twenty-two unselected cases of lobar pneumonia have been treated with unconcentrated type specific antipneumococcus rabbit serum. Ten patients had type I pneumonia, four had type II, three had type VII and

TABLE 5.—*Type Specific Antipneumococcus Rabbit Serum Therapy in Pneumococcus Pneumonia*

Type	Cases	Bacteremia, Number of Cases	Pleural Exudate, Number of Cases	First Serum After Onset, Average Hours	Crisis After First Serum, Average Hours	Serum, Average Cc.	Mortality, per Cent
I	10	8	1	42	23	124	0
II	4	1	2	74	42	231	25
VII	3	1	0	33	19	145	0

Total	22	12	3	46	26	159	4.5

five had type VIII. Of the twenty-two patients, twelve had pneumococcus bacteremia, seven had consolidation of two or more lobes, five were sufficiently ill to require treatment in the oxygen chamber, three had bilateral consolidation and three had pleural exudates containing large numbers of pneumococci. This series is summarized in table 5.

The average total dosage of antipneumococcus rabbit serum, irrespective of the type, was 159 cc. per case: 124 cc. for type I, 231 cc. for type II, 145 cc. for type VII and 173 cc. for type VIII. It is of interest that in 371 patients with type I pneumonia treated at the Hospital of the Rockefeller Institute the average total dosage of unconcentrated horse serum was 420 cc. per case.^{2a} In almost every instance the temperature, pulse and respiratory rates fell to normal a few hours after the administration of rabbit serum and the clinical signs of toxicity were entirely relieved. The average interval from the institution of serum therapy to the termination of the crisis was twenty-six hours, and consequently the acute signs of the disease had disappeared after an average of seventy-two hours from the initial onset of the pneumonia.

It is worth while pointing out that the fall in temperature in the four cases of type II pneumococcus pneumonia was delayed for an average of forty-two hours after the beginning of serum therapy and that more serum was required for this type than for any other treated.

No evidence of sensitivity to rabbit serum on intravenous injection was found in any of the patients treated. Almost invariably the skin tests with normal rabbit serum were positive, but intravenous tests did not produce significant fall in blood pressure or any other sign suggesting hypersensitiveness. No immediate symptoms have followed the intravenous injection of 125 cc. of undiluted rabbit serum in a period as short as ten minutes. The chill reactions, which in the early cases frequently occurred an hour after the first and second and occasionally the third dose of serum, have latterly been eliminated by the oral administration of acetylsalicylic acid (0.9 Gm.) simultaneously with the first injection of serum. It must be reemphasized that the serum was heated to 56 C. for thirty minutes and after cooling was absorbed with sterile kaolin for fifteen hours at 4 C. Since the institution of these procedures chills have been abolished, and the administration of serum has thereby been made far more rapid and the single doses have been larger than was considered advisable in the beginning.

Sabin and Wallace¹⁷ studied the effects of a large number of drugs, including the various antipyretics, on the chill reactions which follow the intravenous administration of horse antipneumococcus serum and concluded that, while nitrites, opium and antipyretics may mitigate the chill reaction, it is doubtful whether they have any practical therapeutic application.

It is highly desirable that the giving of antipneumococcus serum should be made as simple and as rapid as possible. With this in view the rate of administration of serum has been gradually increased in this series of cases with the hope of accomplishing adequate serum therapy with one injection. Actually the last three patients (cases 10, 17 and 22) were treated in this way and, excluding the initial intravenous test doses of 0.1 cc. and 2.0 cc., all received what was thought to be an adequate amount of serum in a single injection. In cases 10 and 17 an additional injection of 40 cc. and 25 cc. respectively was given a few hours after the first injection. It is considered possible that, after additional experience with the various types of immune rabbit serums has been acquired, most cases of lobar pneumonia can be adequately treated with one intravenous injection.

Of the three patients whose pleural exudates were grossly infected with pneumococci, sterilization occurred in two after the intravenous administration of serum, and the fluid was absorbed without the necessity of surgical drainage. In these two exudates the presence of type specific antibodies was readily demonstrable after serum therapy and it was possible by appropriate precipitin and absorption tests to determine that the antibody was of rabbit origin. In the remaining case no antibody was demonstrated in the exudate, and loculated empyema supervened and necessitated surgical intervention. Five weeks after the onset of the disease this patient died following rupture of an aneurysm of the thoracic aorta—the only death in the series. The two cases, one type I and one type II, in which recovery without empyema occurred in spite of initially infected pleural exudates seem worthy of additional consideration. One of the primary indications leading to the clinical trial of antipneumococcus rabbit serum was the apparent small size of the rabbit antibody as compared with that from the horse. The diameter of the former is certainly no greater than one third to one

fourth the diameter of the latter.¹⁸ Since pneumonic consolidation is primarily an extravascular lesion, as too are most of the infective complications resulting from or associated with it, any specific therapeutic agent that is to act locally in the lesion or against its causative agent must do so after penetrating the capillary endothelium. Since the ease with which substances penetrate or diffuse through semipermeable membranes, such as the capillary endothelium, is related in part to their physical size, it seemed reasonable to assume that the rabbit antibody should, by virtue of its smaller size, penetrate into both the pulmonary lesion and the pleural cavity with considerably greater ease and speed than could the horse antibody. In two instances at least this assumption has been found correct, since after the intravenous injection of rabbit serum antibody became readily demonstrable in the pleural fluid. In these two cases the infecting pneumococci disappeared from the pleural exudate and empyema did not occur. After the intravenous injection of horse antiserum it is known that antibody does not diffuse into the pleural space.¹⁹

Twenty-one of the twenty-two patients treated made a complete recovery. Convalescence was on the whole rather uneventful. Mild urticarial serum sickness occurred in twelve of the twenty-two, and in one popliteal thrombophlebitis developed. This was not followed by other sequelae.

SUMMARY

1. Twenty-two patients with lobar pneumonia have been treated with unconcentrated type specific rabbit antipneumococcus serums: ten with type I, four with type II, three with type VII and five with type VIII pneumococcus pneumonia.

2. Pneumococcic bacteremia was present in twelve of the twenty-two, consolidation of two or more lobes in seven, bilateral consolidation in three and pleural exudate containing large numbers of pneumococci in three.

3. Twenty-one patients recovered and one patient died of rupture of the aorta five weeks after the onset of the disease. Recovery was rapid and by crisis in almost all, and the signs of intoxication disappeared shortly after serum therapy. Crisis occurred after an average of twenty-six hours following the institution of serum therapy, and latterly in five cases with the more rapid administration of serum this period has been decreased to an average of nine hours.

4. Empyema did not develop in two patients with grossly infected pleural exudates. Type specific antibody of rabbit origin was demonstrable in these exudates after the intravenous administration of serum, and following this the pneumococci disappeared. Empyema occurred in one patient. In this case, type specific antibody was not demonstrable in the exudate and the pleural infection progressed, necessitating surgical drainage.

5. From these results it appears that unconcentrated type specific antipneumococcus rabbit serum is at least as effective as concentrated horse serum in the treatment of lobar pneumonia. This fact when added to the relative rapidity and ease with which it can be produced, the relatively low cost of the finished product, the facility with which it can be administered, as well as the evidence indicating that rabbit antibody can penetrate the pleura and assist in the sterilization of an infected exudate would suggest that type specific antipneumococcus rabbit serum is a therapeutic agent of considerable promise.

SUMMARY OF CASES

CASE 1.—A white man, aged 57, was admitted sixty hours after typical onset of type I pneumococcus pneumonia. X-ray examination showed consolidation of the right upper, right middle and right lower lobes. The white blood cells numbered 12,300. Blood culture yielded type I pneumococcus, 62 colonies per cubic centimeter. Pleural exudate contained large numbers of type I pneumococcus. Treatment in the oxygen chamber was necessary. Unconcentrated rabbit type I antipneumococcus serum therapy was begun three hours after admission. A total of 112 cc. of serum was given intravenously in the next ninety-four hours. The skin test became positive with type I polysaccharide. The temperature, pulse and respiratory rate dropped to normal by crisis ninety-five hours after the beginning of serum therapy (158 hours after the onset of pneumonia). Following this the temperature did not exceed 101.4 F. Convalescence was slow but progressive improvement occurred. Type I antibodies were demonstrated in the pleural exudate after the termination of serum therapy, and empyema did not develop. The pleural exudate became sterile and was slowly absorbed. Serum disease did not occur.

CASE 2.—A white woman, aged 36, was admitted ninety-eight hours after typical onset of type I pneumococcus pneumonia. X-ray examination showed dense consolidation of the right middle, right lower and left lower lobes. White blood cells numbered 6,800. Blood culture yielded type I pneumococcus, 4 colonies per cubic centimeter. The pleural exudate was sterile. The patient required treatment in the oxygen chamber. Unconcentrated rabbit type I antipneumococcus serum therapy was begun three hours after admission. A total of 115 cc. of serum was given intravenously in the next eighteen hours. The skin test with type I polysaccharide became positive. The temperature, pulse and respiratory rate dropped to normal by crisis twenty-four hours after the beginning of serum therapy (125 hours after the onset of pneumonia). On the following day there was a slight secondary rise in temperature to 101.8 F. and on the next day another rise in temperature to 100.9 F. Convalescence was uneventful. Serum sickness did not develop. The pleural exudate was rapidly absorbed.

CASE 3.—A white man, aged 30, entered the hospital twelve hours after the onset of type I pneumococcus pneumonia. X-ray examination revealed consolidation of the left lower and left upper lobes. The white blood cells numbered 3,900. Blood culture yielded type I pneumococcus, 1 colony per cubic centimeter. The patient was an alcoholic and rapidly became irrational and cyanotic. Unconcentrated type I antipneumococcus rabbit serum therapy was instituted three hours after admission. A total of 220 cc. of serum was given intravenously over a twenty-hour period. The skin test with type I polysaccharide became positive. There was a critical fall in temperature thirty-nine hours after the commencement of serum therapy (fifty-four hours after the onset of pneumonia). There was a slight evening rise in temperature on the three succeeding days. Convalescence was uneventful.

CASE 4.—A white boy, aged 8 years, was admitted thirty-eight hours after sudden onset of type I pneumococcus pneumonia. X-ray examination showed consolidation of the left lower lobe. The white blood cells numbered 22,000. Blood culture was sterile. Unconcentrated type I antipneumococcus rabbit serum therapy was instituted one hour after admission. A total of 32 cc. of serum was administered intravenously in four hours. The skin test with type I polysaccharide became positive. The temperature, pulse and respiratory rate fell by crisis to normal twelve hours after the beginning of serum therapy (fifty-one hours after the onset of pneumonia) and there was no secondary rise.

CASE 5.—A white man, aged 54, was admitted forty-two hours after typical onset of type I pneumococcus pneumonia. The patient had hyperchromic macrocytic anemia. X-ray examination showed consolidation of the right lower lobe. The white blood cells numbered 12,300. Blood culture yielded type I pneumococcus, 1 colony per cubic centimeter. Unconcentrated type I antipneumococcus rabbit serum therapy was begun two hours after admission. A total of 160 cc. of serum was given intravenously in sixteen hours. The skin test with type I polysaccharide remained negative. The temperature, pulse and respiration fell to normal ten hours after serum therapy was begun (fifty-four hours after onset of pneumonia). A mild urticarial serum sickness occurred eight days after admission.

CASE 6.—A white man, aged 29, was admitted thirty-six hours after typical onset of type I pneumococcus pneumonia. X-ray examination showed consolidation of the right middle and left lower lobes. The white blood cells numbered 18,300. Blood culture yielded type I pneumococcus, less than 1 colony in each 2 cc. of blood. Serum therapy was delayed until twelve hours after admission because of a positive skin test to type I polysaccharide. A total of 117 cc. of unconcentrated type I antipneumococcus rabbit serum was given intravenously over a seven hour period. The temperature, pulse and respiratory rate fell to normal by crisis fifteen hours after the beginning of serum therapy (sixty-two hours after the onset of pneumonia). A secondary rise in temperature to 101.2 F. occurred on the evening of the day of crisis. Convalescence was uneventful except for a mild postfebrile psychosis of three days' duration. Serum sickness did not occur.

CASE 7.—A white man, aged 50, was admitted twenty-eight hours after typical onset of type I pneumococcus pneumonia. X-ray examination showed consolidation of the right lower lobe. The white blood cells numbered 19,400. Blood culture was sterile. Unconcentrated type I antipneumococcus rabbit serum therapy was begun one hour after admission. A total of 140 cc. of serum was given intravenously in fifteen hours. The skin test with type I polysaccharide became positive. The temperature, pulse and respiratory rate fell to normal by crisis fourteen hours after the beginning of serum therapy (forty-four hours after the onset of pneumonia). A secondary rise of temperature to 102.8 F. occurred on the evening of the day of crisis. Moderately severe serum sickness with both skin and joint manifestations began on the eighth day following serum. Convalescence was complicated by thrombophlebitis involving the left popliteal vein. Resolution of this process occurred without incident.

CASE 8.—A white woman, aged 39, was admitted thirty-two hours after the onset of type I pneumococcus pneumonia. X-ray examination showed consolidation of the left upper lobe. The white blood cells numbered 16,400. Blood culture yielded type I pneumococcus, 3 colonies per cubic centimeter. An electrocardiogram revealed complete heart block. Unconcentrated type I antipneumococcus rabbit serum therapy was started two hours after admission. A total of 140 cc. of serum was given intravenously in twelve hours. The skin test became positive to type I polysaccharide. The temperature, pulse and respiratory rate came to normal by crisis fourteen hours after the beginning of serum therapy (forty-eight hours after the onset of pneumonia). No secondary rise in temperature occurred. Convalescence was uncomplicated.

CASE 9.—A white man, aged 42, was admitted thirty-two hours after typical onset of type I pneumococcus pneumonia. X-ray examination showed consolidation of the right lower lobe. The white blood cells numbered 25,800. Blood culture yielded type I pneumococcus, less than 1 colony in each 2 cc. of blood. Unconcentrated type I antipneumococcus rabbit serum therapy was begun two hours after admission. A total of 90 cc. of serum was given intravenously in a three hour period. The skin test with type I polysaccharide was equivocal. The temperature, pulse and respiratory rate fell to normal by crisis six hours after the beginning of serum therapy (forty-one hours after the onset of pneumonia). A secondary rise in temperature did not occur. Convalescence was uneventful. Serum sickness did not occur.

CASE 10.—A white woman, aged 50, was admitted eleven hours after the beginning of type I pneumococcus pneumonia. X-ray examination showed consolidation of the right lower lobe. The white blood cells numbered 14,800. Blood culture yielded type I pneumococcus, less than 1 colony per cubic centimeter. Unconcentrated type I antipneumococcus rabbit serum treatment was undertaken three hours after entry. A total of 120 cc. of serum was administered intravenously in three hours. The skin test became positive to type I polysaccharide. The temperature and pulse rate reached normal five hours after the beginning of serum treatment (nineteen hours after the onset of pneumonia). For the following fourteen days the patient had a low grade fever. Moderately severe urticarial serum sickness developed eight days after the beginning of serum therapy. Sterile pleural exudate was found to contain type I antibody. Resolution was slow.

CASE 11.—A white woman, aged 60, was admitted thirty-six hours after typical onset of type II pneumococcus pneumonia.

X-ray examination showed consolidation of the left lower lobe. The white blood cells numbered 16,100. Blood culture yielded type II pneumococcus, 8 colonies per cubic centimeter. Auricular fibrillation was present. Unconcentrated type II antipneumococcus rabbit serum therapy was begun fourteen hours after admission. A total of 179 cc. of serum was given intravenously in twenty-four hours. The skin test became positive to type II polysaccharide. The temperature declined by lysis over a period of twenty-four hours. In the succeeding three days an additional 80 cc. of serum was given because of secondary rises in temperature. Mild urticarial serum sickness occurred eight days after serum administration. Type II pneumococcus empyema developed on the eighth day of disease and was treated by rib resection and drainage. Type II antibody was not demonstrable in the pleural exudate. The patient died suddenly thirty-eight days after admission from rupture of a dissecting aneurysm of the thoracic aorta.

CASE 12.—A white woman, aged 36, was admitted thirty-six hours after typical onset of type II pneumococcus pneumonia. X-ray examination showed consolidation of the right lower lobe. The white blood cells numbered 22,800. Blood culture was sterile. Unconcentrated type II antipneumococcus rabbit serum therapy was instituted sixteen hours after admission. A total of 155 cc. of serum was given intravenously in the next eighty hours. The skin test became positive to type II polysaccharide. The temperature, pulse and respiratory rate fell to normal by crisis sixty-eight hours after the beginning of serum therapy (120 hours after the onset of pneumonia). No secondary rise in temperature occurred. Convalescence was rapid and uneventful except for very mild urticarial serum sickness, which developed ten days after the beginning of serum.

CASE 13.—A white youth, aged 19, was admitted forty-eight hours after the abrupt onset of type II pneumococcus pneumonia. The patient was an alcoholic addict. X-ray examination revealed consolidation of the right lower lobe, which spread rapidly to involve both the right middle and the right upper lobe. The white blood cells numbered 20,000. Blood culture was sterile. Unconcentrated type II antipneumococcus rabbit serum treatment was begun one hour after admission. A total of 268 cc. of serum was injected intravenously within a period of thirty hours. Falling blood pressure and cyanosis required the administration of oxygen in the chamber. The skin test became positive to type II polysaccharide. The temperature and pulse rate reached normal levels sixty-eight hours after the beginning of serum therapy (117 hours after the onset of pneumonia). Pleural exudate during the febrile stage contained large numbers of type II pneumococci. After the intravenous administration of serum, type II antibody of rabbit origin became demonstrable in this exudate and the pneumococci disappeared. The exudate was rapidly absorbed and convalescence was uneventful, except for mild urticarial serum sickness that developed after five days. The subsequent course was uneventful.

CASE 14.—A white man, aged 50, was admitted 144 hours after an acute onset of type II pneumococcus pneumonia. X-ray examination showed massive consolidation of the right upper lobe. The white blood cells numbered 18,900. Blood culture was sterile. Unconcentrated type II antipneumococcus rabbit serum therapy was instituted one hour after admission. A total of 210 cc. of serum was given intravenously in six hours. Marked cyanosis necessitated the administration of oxygen. There was also slight jaundice. The skin test became positive to type II polysaccharide. The temperature, pulse and respiratory rate fell to normal seven hours after the beginning of serum treatment (152 hours after the onset of pneumonia). Moderate secondary rises in temperature, unaccompanied by signs of intoxication, occurred on eight succeeding days. There was no pleural exudate but resolution was markedly delayed. Mild urticarial serum sickness with slight arthralgia occurred after fourteen days.

CASE 15.—A white man, aged 35, was admitted thirty-two hours after a typical onset of type VII pneumococcus pneumonia. X-ray examination revealed consolidation of the right upper lobe. The white blood cells numbered 18,000. Blood culture yielded type VII pneumococci, 1 colony in each 2 cc. Unconcentrated type VII antipneumococcus rabbit serum therapy was commenced five hours after admission, and 164 cc. of serum was given intravenously in thirty-five hours. The temperature, pulse and respiratory rate fell to normal by crisis thirty-nine hours after the beginning of serum therapy (seventy-

six hours after the onset of pneumonia). Convalescence was interrupted only by slight urticaria and transitory joint stiffness, which developed nine days after the beginning of serum therapy.

CASE 16.—A white man, aged 32, was admitted twenty-eight hours after atypical onset of type VII pneumococcus pneumonia. The patient was deeply jaundiced. X-ray examination showed consolidation of the right lower lobe. The white blood cells numbered 14,200. Blood culture was sterile. Unconcentrated type VII antipneumococcus rabbit serum therapy was begun six hours after admission. A total of 122 cc. of serum was given intravenously in four hours. The temperature, pulse and respiratory rate fell to normal by crisis eleven hours after the beginning of serum therapy (forty-five hours after the onset of pneumonia). Jaundice disappeared quickly following deferescence, but mild serum sickness appeared seven days after administration of the serum. A sterile effusion occurred into the right pleural cavity during convalescence but was rapidly absorbed.

CASE 17.—A white man, aged 60, was admitted twenty-seven hours after the onset of type VII pneumococcus pneumonia. X-ray examination showed a consolidation of the right upper lobe. The white blood cells numbered 9,750. Blood culture was sterile. Unconcentrated type VII antipneumococcus rabbit serum therapy was begun one hour after admission. A total of 150 cc. of serum was injected intravenously in twelve hours. The temperature, pulse and respiratory rate reached normal nine hours after the commencement of serum therapy (thirty-seven hours after the onset of pneumonia). On the following five days there was a slight evening elevation of temperature. Convalescence was uninterrupted except for urticarial serum sickness, which developed four days after the beginning of serum treatment and recurred six days later.

CASE 18.—A white woman, aged 51, was admitted twenty hours after typical onset of type VIII pneumococcus pneumonia. X-ray examination showed consolidation of the right upper lobe. The white blood cells numbered 27,400. Blood culture yielded type VIII pneumococcus, 2 colonies per cubic centimeter. Oxygen therapy was necessary. Unconcentrated type VIII antipneumococcus rabbit serum therapy was begun three hours after admission. A total of 185 cc. of serum was given in the next twenty hours. The temperature, pulse and respiratory rate fell to normal by crisis thirty-three hours after the institution of serum therapy (fifty-six hours from the onset of pneumonia). No secondary rise in temperature occurred. Convalescence was uneventful except for extensive urticarial serum sickness, which developed six days after the beginning of serum.

CASE 19.—A white man, aged 24, was admitted twenty-four hours after onset of type VIII pneumococcus pneumonia. X-ray examination revealed consolidation in the right lower and left lower lobes. The white blood cells numbered 9,200. Blood culture was sterile. Unconcentrated Type VIII antipneumococcus rabbit serum treatment was undertaken two hours after entry. A total of 267 cc. of serum was given during a period of thirty-three hours. The temperature, pulse and respiratory rate fell precipitously to normal forty-three hours after the beginning of serum therapy (sixty-nine hours after the onset of pneumonia). No secondary rise in temperature occurred. Serum sickness did not occur. Convalescence was uneventful.

CASE 20.—A white youth, aged 15, was admitted seventy-two hours after typical onset of type VIII pneumococcus pneumonia. X-ray examination showed consolidation of the left upper lobe. The white blood cells numbered 7,900. Blood culture was sterile. Treatment with unconcentrated type VIII antipneumococcus rabbit serum was begun two hours after admission. A total of 135 cc. of serum was given intravenously in seventeen hours. The temperature, pulse and respiratory rate fell to normal by crisis nineteen hours after the beginning of serum therapy (ninety-three hours after the onset of pneumonia). No secondary rise in temperature occurred. Convalescence was uneventful except for very mild urticarial serum sickness which developed twelve days after administration of the serum.

CASE 21.—A white woman, aged 56, was admitted twenty-eight hours after typical onset of type VIII pneumococcus pneumonia. X-ray examination showed consolidation of the right upper lobe. The white blood cells numbered 26,800. Blood culture yielded type VIII pneumococcus, less than 1 colony in

each of 2 cc. of blood. Unconcentrated type VIII antipneumococcus rabbit serum therapy was begun two hours after admission. A total of 150 cc. of serum was given intravenously in four hours. The temperature, pulse and respiratory rate fell to normal by crisis twelve hours after the beginning of serum therapy (forty-two hours after the onset of pneumonia). Transient urticaria appeared ten days after the serum was given. Convalescence was uneventful.

CASE 22.—A white woman, aged 68, was admitted thirty-eight hours after typical onset of type VIII pneumococcus lobar pneumonia. X-ray examination showed consolidation of the right lower lobe. The white blood cells numbered 20,000. Blood culture was sterile. A total of 127 cc. of unconcentrated type VIII antipneumococcus rabbit serum was given intravenously in a single injection two hours after admission. The temperature, pulse and respiratory rate fell to normal by crisis twelve hours after injection of the serum (fifty-two hours after the onset of pneumonia). No secondary rise in temperature occurred. Convalescence was uneventful. Serum sickness did not develop.

Sixty-Sixth Street and York Avenue.

THE RATIONALE OF THE TANNIC ACID-SILVER NITRATE TREATMENT OF BURNS

ADALBERT G. BETTMAN, M.D.

Clinical Associate in Surgery, University of Oregon Medical School
PORTLAND, ORE.

A new conception of burns has been brought about as a result of their treatment by the tannic acid-silver nitrate method.¹ This treatment appears to change the lesion into one comparable to a surgical wound. It is this induced change, by the application of tannic acid and silver nitrate, that makes it superior to any other procedure from many different points of view:

1. The saving of lives that would be lost through the slower method of tanning.
2. The immediate stopping of the loss of body fluids, thereby preventing the consequent concentration of the blood.
3. The immediate prevention or very definite minimizing of shock.
4. The immediate prevention of the absorption of toxic products.
5. The prevention of infection by the short period of application of moisture and the early drying of the tanned tissues.
6. The saving of the kidneys and other organs from the effects of fluid concentration and the absorption of toxins and infection.
7. The greater comfort of the patient.
8. The fact that the patient is carried safely past the first twenty-four hours, the most critical period following a serious burn.
9. The fact that the patient avoids the second critical period, that of infection and late absorption of toxic products.
10. The simplification of the nursing problem, especially in the first twenty-four hours.
11. The prevention of further breaking down of tissues, resulting from long application of wet dressings.
12. The prevention of chilling, resulting from the long application of cold, wet dressings.
13. The formation of a thin, flexible coagulum.
14. The speedy healing of the burned areas with a shortened period of hospitalization.
15. The prevention or minimizing of heavy contracting scars by early rapid healing in the absence of infection.
16. The lessening of the amount of skin grafting and secondary corrective surgery.

From the Department of Surgery, University of Oregon Medical School.

Read before the Eastern Oregon District Medical Society, La Grande, June 27, 1936.

1. Bettman, A. G.: The Tannic Acid-Silver Nitrate Treatment of Burns, *Northwest Med.* 34: 46-51 (Feb.) 1935; Tannic Acid and Silver Nitrate in Burns, *Surg., Gynec. & Obst.* 62: 458-463 (Feb., No. 2A) 1936.

In July 1934 I used the tannic acid and silver nitrate method for the first time on an extensive burn, the seventh burn on which it was used, although I had for many years used the same agents for the removal of tattooing. The result was the spectacular recovery of a doomed man. Previous presentations have dealt solely with the details of the application of the treatment. The present paper is a consideration of its rationale.

A burn lesion is not the burn alone but the burn plus all those consequences which develop because the treatment does not check them. The outcome of the treatment has in the past too often been considered as an unavoidable part of the original condition. Accordingly the treatment of serious burns has been approached with dread by physicians because of the limited benefits accruing from their management.

When tannic acid is applied to a burn and is followed by silver nitrate, a coagulum speedily forms which becomes impermeable to the further loss of body fluids and which immediately prevents additional fluid shifts. Through its speed alone in producing this change, it saves lives. This treatment by preventing dehydration minimizes shock and thereby carries the patient safely through the most critical period; that is, the first twenty-four hours following a serious burn. It therefore lessens one of the most fatal untoward effects of a burn.

A burn, however produced, results in injury to, or destruction of, the skin to a greater or less depth, frequently extending into the subjacent tissues. This injury to the outer protecting layer of the body quickly results in the formation of large or small vesicles, which may remain intact or which may become ruptured and ooze for a long time. Following a burn there begins at once the outpouring from the surface of the body of a great quantity of fluid. The loss of the outer layers of skin, those which act as a seal, allows this to take place unhindered. This serum loss rapidly reduces the amount of all body fluids. The removal of the protective layers of the skin alone by any means, including burns, results in a copious outflowing of serum. Such weeping outlets must be sealed at once to prevent dehydration.

In addition to the surface escape of fluid there is produced very early a reaction which calls for the pouring out of circulating body fluids into the tissues adjacent to the thermal injury. This local stagnation of fluids is also very large. Escape of fluid by means of the action of the sweat glands must also be added. These combined losses of circulating body fluids, namely, that which oozes from the body and that which stays in the tissues, is therefore not only voluminous but consequential, since Blalock,² Parsons and Phemister,³ Harkins,⁴ Underhill, Kapsinow and Fisk⁵ and

Med.* 16: 823 (May) 1931.

many other investigators have shown that traumatic shock is the result of the diminution and shift in circulating body fluids.

A brief review of some of the major points brought out by these experimenters is of interest. Animals were fixed on their backs in a trough suspended from above, in such a manner that the apparatus just balanced and was attached to a revolving, recording drum. Severe injury without bleeding was then produced to one side of the animal by burning or beating. Very shortly that side of the apparatus became heavier than the other. This shift of body fluids began promptly. Forty per cent of the maximum shift occurred within the first hour after the injury and continued in a gradually decelerating curve. In the course of these experiments the amount of circulating fluids lost was estimated in various ways: (1) by balancing the overweight of the burned side with weights on the opposite side and (2) by weighing separately the two sides of the animal after death. These authors further showed that the amount of blood obtained by bleeding an animal under an anesthetic is an index of the circulating blood volume. In control dogs the bleeding volume averaged over 55 per cent of the calculated circulating blood volume. In shock due to severe trauma of the extremities, whether caused by a burn or otherwise, it was reduced to as much as 16 per cent. The shift from the circulating blood stream to and about the injured tissues consisted therefore of a very large percentage of the circulating blood volume. The figures representing the circulating fluid loss were further substantiated by excising sections of muscle from the injured and the uninjured side, weighing them and then evaporating them to dryness, and also by expressing the fluids under pressure. The same figures were obtained. These determinations were still further checked by frequent hemoglobin estimations and hemocrit readings and were compared with control animals similarly anesthetized but otherwise uninjured.

The average loss of circulating body fluids following a severe burn was found to be 2.1 per cent of the total body weight. As dogs do not blister and weep, this loss was solely into and about the injured tissues. It was out of the circulation though not out of the body. The deprivation of a large volume of circulating body fluids is therefore shown to be the direct cause of shock, which will become manifest when the fluid reaches a certain low point. However, other factors may increase it. Other experimental evidence also shows that the blood pressure holds up fairly well until shortly before death. It falls only after the heart output is reduced, when shock supervenes. The blood pressure is therefore not a reliable criterion of the condition of the burned patient. Hemoglobin determinations, on the other hand, give much more reliable information and should be made frequently. The fluid that escaped into subcutaneous tissues after an experimental burn showed some chloride increase over the fluid portion of the blood. Sugar and nonprotein nitrogen were not changed, and the protein content was somewhat lower. It very closely resembled blood plasma.

It follows, then, that when a part is burned or otherwise injured there is produced in and about that area an altered physiology. A call goes forth that results in a rapid and great seeping of fluids into, and adjacent to, the injured area. A considerable fluid loss thereby is rapidly attained. However, when such a traumatized region is treated at once by the application of tannic acid followed by silver nitrate, all the destroyed and

injured tissues down to the very borderline of impaired cells are picked up and fixed in an innocuous, nonabsorbable coagulum.

The shift of the circulating body fluids into the tissues adjacent is halted at once. The necessity for prompt and complete stoppage of all fluid losses is imperative. A treatment that requires more than an hour in which to seal up the leaking surfaces and to control the fluid shift is therefore to a high degree inefficient. Tannic acid and silver nitrate applications which act instantly are therefore most efficient. The practical importance of speed in the initial treatment of burns is manifest when it is recalled that 60 per cent of the deaths from burns occur in the first twenty-four hours, nearly all from traumatic shock.

What are the practical applications of the foregoing facts to a man of say 155 pounds (70 Kg.)? The calculated blood volume, being one thirteenth of the body weight, is therefore 12 pounds (5.4 Kg.). The total amount of circulating body fluids is about 60 per cent of the calculated blood volume, or 7.2 pounds (3,266 Gm.). The loss of 2.1 per cent of the total body weight therefore would be $3\frac{1}{4}$ pounds (1,474 Gm.). Thus is lost between 40 and 50 per cent or even a greater amount of the entire fluid portion of the blood. It was also determined by comparison with experimental animals that a burn of one sixth of the body surface of a 150 pound (68 Kg.) man may cause a loss of 3,500 cc. or 70 per cent, a staggering amount, of the circulating body fluids in the first twenty-four hours.

The efforts of nature to overcome an injury by dilution of the obnoxious agent call for the outpouring of fluid into the surrounding and adjacent tissues. This produces edema of the intercellular spaces and widespread swelling. When tannic acid and silver nitrate are applied, the seal they provide exerts an influence that is beneficial beyond anticipation. The changes in the surface come with great promptitude. What was but a moment ago a red, wet, oozing, irritated surface is now covered with a black, smooth, dry, leatherized eschar, soft and flexible, yet firmly attached and acting as a protection from injury from without, as well as being an occlusant against the loss of fluids from within. The usual widespread and important systemic effects of the burn are not noted. Untoward reactions are absent and the picture is entirely different from that seen when other treatments are used.

With this treatment, the temperature usually does not rise above 101 F. even in extensive burns, and the pulse and respiratory rates are proportionately low. The red blood cell counts remain remarkably near normal, as do also the white cell counts. Only a few staff cells are present.

Gunn and Hillsman⁶ state that kidney damage occurs so regularly and so early that it may be taken as a part of the phenomena of burns and not be classed as a complication. Yet, when the tannic acid-silver nitrate treatment has been used, urinary suppression has never been seen, nor has albumin been present, or other abnormal elements, in the absence of grease or oil applications, except sugar, which may be present in the early specimens following any burn. The minimal systemic effects are a notably outstanding feature of this regimen.

When wet solutions are applied to tissues, normal or injured, over a long period, there is produced a reaction which is threefold: edema, maceration and infection. The presence of fluid, tannic acid solution, saline solu-

6. Gunn, J., and Hillsman, J. A.: Thermal Burns, *Ann. Surg.* 102: 429-443 (Sept.) 1935.

tion or what not, in contact with tissues over many hours is responded to by a dilatation of the neighboring blood vessels and an outpouring of fluid into the tissues. In addition, there is absorption of portions of the fluid into and about the injured area. A combination of these actions, therefore, results in the escape of increased amounts of fluids into the intercellular spaces. These spaces, becoming engorged, produce a very considerable enlargement of the extremity. This takes place when for example wet packs are applied as to a hand. However when tannic acid and silver nitrate are applied, the period of the application being but a few minutes at most, there is not time for the dilatation of vessels, for the outpouring of fluids from the circulation, for the absorption of fluids from the surface or for weeping.

Substances such as may be present as a result of the tissue destruction and which may produce local reactions causing intercellular edema are grasped and held at once permanently in an insoluble, nonabsorbable, irreversible matrix. There are therefore no irritating substances beneath the coagulum to call out a reactive response. There is no outpouring of fluid, no oozing, no overfilling of the intercellular spaces, no edema, no enlargement of the extremities and no increase of pressure within the coagulum. There are no toxins or other deleterious substances to be absorbed.

In practically all burns there remain unimpaired many epithelial islands of skin and of the deep glands. The long application of any solution breaks down many or all of these. Tannic acid and silver nitrate save these centers of epithelialization, and speedy healing with lessened scar tissue is therefore promoted.

By the use of tannic acid and silver nitrate, there being no fluid on the surface for long periods and the casing formed being dry, nonabsorbable and of a composition which is not a good culture medium, infection is prevented. The wound is dry and clean from the onset and is kept so throughout.

Contrariwise, when grease or oil in any form has been applied, whether as the burning agent or as the treatment, even though complete removal is attempted, there will remain areas which are not as dry as when grease has not been applied. Grease and oil applications should never be made to any burn.

When slow acting coagulating applications are made there is much edema, which progressively increases the tension of the tissues within the slowly forming casing. The application of tannic acid followed by silver nitrate produces an eschar under which there is little or no increased tension. An objection to the use of tannic acid alone is the loss of digits, which sometimes occurs. The marked difference in the tannic acid alone and the tannic acid-silver nitrate treatment in this regard is distinctly shown in the cases to be cited:

CASE 1.—Baby C., aged 5 months, received a burn of the entire right upper extremity, the chest and the face. The tannic acid-silver nitrate treatment had not yet been used on extensive burns and was used only on the chest. Tannic acid alone was used on the extremity and the face, according to established technic. The leatherization took place over a period of some hours, with another period for drying. During the time that the coagulum was forming an outpouring of serum from the surface as well as into the subcutaneous and deep tissues was taking place, as was also some absorption of fluid from the surface. These actions continued concurrently with the formation of the leatherized encasement, and the extremity became confined within a slowly forming but nevertheless firm case. The edema progressively increased and the pressure within the casing increased with it and finally became sufficiently great so that the venous return flow was impeded, as was also the arterial circulation. The hand sloughed off at the wrist just

below the point at which the circulation was superficial and therefore most easily compressed.

CASE 2.—R. B., a man, aged 45, received a 54 per cent (by actual measurement) gasoline burn extending from the top of his head to his right ankle. He was seen shortly after patient 1. So seriously burned was he that three physicians told him that his condition was hopeless. The burn of the hand and arm was more severe than that of the child, and his general condition was also very much worse. When I saw him four hours after the accident a considerable loss of circulating body fluids had already taken place. The hemoglobin was 165 per cent of normal and the red blood cell count showed concentration in proportion. Tannic acid was applied from head to foot, followed by silver nitrate. The oozing was stopped almost instantaneously and within a few minutes the surface was dry and there was no further increase of the dehydration. Albumin was never present in the urine. The outpouring of serum into the adjacent tissues was also stopped with promptitude. Encasement of more than half of the body surface, including the entire right arm and forearm, both wrists and hands and right leg and thigh, head, back and other parts, was quickly accomplished. A firm, dry, thin, leather-like covering was formed. The blood vessels of the wrists and elsewhere were not impinged on and the circulation of the burned extremities was not interfered with. There was little or no increase of pressure within the casings. The passage of but a few days showed that both hands with all fingers would be saved intact. He was all healed and well by the forty-second day and today has no impairment of function of the fingers and hands and no scarring anywhere except on the back of the right hand and forearm, where Thiersch grafts were applied on the twenty-sixth day.

The contrast of these two cases is very vivid. Not only was this life saved by the prompt action of the medicaments but his hands also by the absence of undue pressure within the rigid encasement which covered the extremities like a glove. It is not intended to convey the idea that digits may never be lost under this treatment, but they are not lost because of edema within the coagulum.

Three cultures taken from beneath unbroken tanned and dry coagulum on two seriously burned patients showed no growth of organisms, but cultures taken from uncovered areas showed *Staphylococcus albus*. The dry surface of treated areas is not a good culture medium for bacteria, and this condition is augmented by the antiseptic action of the silver present in the coagulum. From early periods silver, both in the metal and in the salts, has had wide usage for the prevention of infection in wounds, and surely it is here applied to a maximum effect.

That no absorption of silver takes place even when extremely large amounts of solution are used is proved by the fact that in none of the many cases treated has argyria or other evidences of silver absorption been seen, although carefully watched for. It has not been noted by other surgeons who have reported experience with this treatment.⁷

Patients treated with tannic acid followed by silver nitrate are remarkably comfortable at once. Many patients are ambulatory from the beginning or at a very early date, frequently even when portions of the lower extremities or the torso are the sites of injury. Even in very extensive burns, patients move about quite freely in bed. The extreme systemic effects of the burn are greatly attenuated. Irrational periods are present only in very large burns and are of short duration.

B.: *The Tannic Acid-Silver Nitrate Treatment of Burns*, New Zealand M. J. 34: 344 (Dec.) 1935. Rambo, V. C., and James, J.: *Treatment of Tropical Ulcers in Leprosy*, J. Christian M. A. India, September 1935. Gentry, J. H.: *Modern Therapy in the Treatment of Burns*, New Orleans M. J. S. J. 88: 575 (March) 1936.

A serious burn affects all the vital organs unless stopped by efficient treatment. When dehydration occurs, it lowers the heart output and makes difficult the carrying on of the vital processes by the blood cells operating in deficient fluids with increased viscosity and resulting anoxemia. The lessened aeration of the blood is the effect of the difficulty in taking on oxygen and giving off carbon dioxide and other waste products. Toxic substances are excreted with difficulty and incompletely. The blood chemistry particularly is changed. The absorption of degenerated tissue and bacterial toxins modifies the action of all the organs and tissues within the body. It is proposed to discuss the blood chemistry phase of this treatment at another time. These untoward effects are not seen when the burn is early treated with tannic acid and silver nitrate as directed.

The treatment of burns with tannic acid alone has proved far superior to greases and oils and other applications. While the use of tannic acid alone, as brought out by Davidson,⁸ is a decided advance over applications of grease and oil, yet it is not comparable to the tannic acid-silver nitrate method. The tannic acid alone and the dye treatments act in hours. Tannic acid followed by silver nitrate controls the condition in minutes. As stated earlier, red blood cells and albumin do not occur in the urine of patients under the tannic acid-silver nitrate regimen in the absence of applications of grease or oil; but when these applications have been made there is always albumin in the urine, even though an attempt has been made to remove them.

In the latter case the deficiency in the stoppage of the fluid loss through weeping and edema is but slightly less than when grease has not been applied, not sufficient to make an appreciable difference in the concentration of the blood, yet this slight surface moisture is enough to permit the entrance into the blood stream of toxins or other elements that are present on the surface and to allow some infection to develop. The absorption of some substance or substances from the surface must account for the presence of the albumin in the urine.

Concentration of the blood by itself is not sufficient to explain the albuminuria, for it does not appear in other conditions in which dehydration is a marked factor, such as cholera, persistent diarrhea, severe hemorrhage and prolonged vomiting. Something other than fluid loss must be responsible for the injury to the kidneys, spleen, liver, adrenals, blood production mechanism and other internal organs. Also, when grease or oil has once been applied the temperature, pulse, respiration, blood counts and the like are increased over what they would have been had such application not been made. The breaking down of protein and the slight infection that develops must account for the presence of substances which are promptly absorbed and which give systemic reactions.

One pictures mentally the terrible painfulness of daily or more frequent dressings of a seriously burned child treated by carron oil or other oil and applications of grease. The infection is always so great beneath the dressings that frequent removals are imperative.

With tannic acid alone the maximum problem of nursing is the often to be repeated applications by swabbing, spraying or packs, with their almost continuous disturbing of the patient. As the coagulum slowly forms the loss of circulating body fluids con-

tinues, and this loss must be made up by repeated intravenous, subcutaneous or rectal administrations of fluid, for the stomach retention is usually at a low point at this time.

With tannic acid followed by silver nitrate, one thorough application of the medication and the patient is allowed to rest in his bed warmed by electric lights, being disturbed only once or twice or maybe three times for the giving of intravenous fluids. Surprisingly early is the mouth intake and the stomach retention sufficient to meet all requirements. Frequent hemoglobin estimations are the simple, easy and ever at hand guide that should determine the amount of the fluid intake. Following a serious burn a minimum of 1,000 cc. of fluids should be given every twenty-four hours for every 25 pounds (11 Kg.) of body weight, and this should be more or less equally divided throughout this period.

In the early part of the first twenty-four hours a very liberal proportion of the fluids should be given, but care is necessary, especially in children, to see that too large a quantity is not given at any one time. The sudden throwing of 500 cc. of fluid into the blood stream of a patient weighing say 50 pounds (23 Kg.), and who normally has but 4 pounds (1,814 Gm.) of blood, would dilute the circulating body fluids 25 per cent or more.

When the hemoglobin reading is nearing normal, care should be used in giving extra-alimentary fluids. A diplomatic nurse will have no difficulty in persuading her patient to take the required amount of water, fruit juices and the like by mouth after the earliest hours, provided it is properly distributed throughout the waking period. The necessity for including salt must not be overlooked, and dextrose also.

Instead of the nurse bending her efforts toward the production of a good coagulum, she has no concern with this feature, as it has already been accomplished by the twofold application, and she therefore spends her time in keeping the patient warm and the coagulum dry and in forcing fluids.

By this procedure the coagulum is formed by the combination of tannic acid with the body fluids and then by a union of the silver nitrate with this first combination. The application of tannic acid produces a grayish white precipitate, which instantly becomes black when in contact with the silver nitrate. Metallic silver is precipitated into the mass, where it is fixed. Any heavy metal would undoubtedly act in much the same way if used when silver nitrate is not available, but the good offices of the silver would be lacking.

Burns treated with oil and grease heal slowly, become infected, form abundant scar tissue and have a long and trying period of hospitalization. The treatment by tannic acid followed by silver nitrate, in the absence of oil and grease, promotes smooth healing. There is little or no infection beneath the coagulum, there is minimum scarring and a short period of hospitalization, frequently none at all, and there are no dressings to be changed. Many patients are entirely healed beneath the coagulum when it comes away.

Our records show that the hospital confinement period has been reduced to one-fourth the time by this treatment. In other words, it takes only weeks now for recovery whereas under former treatments months were required.

The tannic acid-silver nitrate treatment of a burn is carried out as follows: The patient is given a narcotic, which is repeated as often as may be necessary

8. Davidson, E. C.: Tannic Acid in the Treatment of Burns, Surg., Gynec. & Obst. 41: 202-221 (Aug.) 1925.

for comfort. Fluids must be forced throughout.⁹ Grease and oil in any form should not be used. If such an application, unfortunately, has been made, it must be removed with ether, benzene or ethyl acetate before treatment is applied. All blebs are to be opened and all loose skin and other burned tissues are to be removed. A thorough application of fresh 5 per cent tannic acid solution is made by means of cotton swabs. Following this, 10 per cent silver nitrate solution is applied in the same manner.

The local treatment now being completed, the patient is placed in a tent heated by electric light bulbs and the burned areas are dried and kept dry. In a few days the coagulum begins to loosen and is removed as early as possible. When it comes away, large areas and not infrequently all the burned surfaces will be found to be entirely healed. Occasionally moisture will be hidden beneath crusts where drying has not been satisfactorily accomplished, and such areas are unhealed. When the coagulum is adherent but loose, it is removed, a scalpel being used if necessary. Unhealed areas are treated by the application of oxyquinoline sulfate scarlet R gauze,¹⁰ in a single layer over which a light pad of dry gauze is placed, and healing is greatly speeded up.

The schedule here outlined—the avoidance of grease and oil, the giving of a narcotic, the application of tannic acid followed by silver nitrate, drying the coagulum, keeping it dry and removing it early, forcing fluids and the stimulation of epithelization—constitutes a superior method of treating serious burns. Less skin grafting and other reconstructive measures are required. There are minimum scars, and greatest of all is the saving of lives that would otherwise be lost.

Medical Arts Building.

NONPARALYTIC POLIOMYELITIS VERSUS CHORIOMENINGITIS

PASCAL F. LUCCHESI, M.D.

Associate in the Pediatric Department, Temple University School of Medicine; Superintendent of the Philadelphia Hospital for Contagious Diseases
PHILADELPHIA

In the summer and fall months of 1935, physicians in and about Philadelphia observed that many of their patients suffered from a disease of the central nervous system which for the most part presented the following picture: The onset was usually acute, with fever, headache, nausea or vomiting forming the chief triad of symptoms. Examination disclosed some stiffness and rigidity of the neck with increased white cells in the spinal fluid, the majority of which were lymphocytes. The febrile period lasted from seven to ten days, declining by lysis and resulting in complete recovery without evidence of weakness or paralysis. Because of the type of onset, the physical changes and the termination of this disease several diagnoses were made, among which may be listed abortive poliomyelitis, encephalitis, meningismus, influenza, aseptic meningitis and the more recent disease referred to by Armstrong and Dickens¹ as acute lymphocytic choriomeningitis.

Since many physicians believed that they were dealing with an atypical or an abortive type of poliomyelitis, it was considered wise to refer such cases to the Phila-

delphia Hospital for Contagious Diseases for observation and study. Accordingly, late in July, patients presenting the aforementioned syndrome were admitted to a ward of the hospital especially assigned to such cases. This ward is equipped with a cubicle system of isolation, each cubicle having its own medical aseptic technic and containing either two beds or two cribs. Up to November 25, sixty-seven persons with these symptoms and signs were admitted, a summary of which is reported in table 1.

It will be seen from a glance at the table that the symptoms and signs most prevalent were fever, headache, nausea, vomiting and stiffness or rigidity of the neck. The headaches were mostly frontal in type and of a persistent character. The rigidity of the neck, the pains in the legs and neck, the backache, the nasal discharge and the action of the deep reflexes were strikingly similar in character to those observed in poliomyelitis.

Table 2 shows that although the largest number (68.65 per cent) of patients affected were under 10 years of age, a goodly number were credited to those of 10 years or more. The youngest patient in this group was 6 months of age and the oldest 26 years. Thirty-six, or 53.73 per cent, were males and thirty-one, or 46.27 per cent, were females. Of this group forty-nine cases, or 73.13 per cent, occurred in the white race and eighteen, or 26.87 per cent, in the colored race.

Fever was not a very striking feature of this disease, for only six (8.96 per cent) had a temperature of 103 F., whereas thirty-six (53.73 per cent) recorded a temperature of 100 F. or less. Twenty-five patients had a temperature ranging between 100 and 103 F. The average duration of fever in fifty of these patients was 7.05 days. However, when this group is divided into those who did not present evidence of weakness or paralysis and those who did, one finds that in the latter group the average duration of fever was 8.92 days while in the former it was 6.04 days. Of the sixty-seven patients seven were afebrile and ten had a fever which lasted more than two weeks. These were not included in calculating the aforementioned averages. The longest duration of fever, in a child with severe respiratory complications was forty-six days while the shortest was one day.

The majority of the patients had an increased spinal fluid pressure, with an abnormal number of white blood cells. The average cell count was 113 per cubic millimeter. The highest cell count recorded was 1,280 per cubic millimeter, while the lowest was 14 per cubic millimeter. The majority of the cells were of the lymphocytic variety, in many cases totaling 100 per cent. The average chloride was 665 mg., sugar 68 mg. and protein 83 mg. per hundred cubic centimeters.

A glance at table 3 shows that thirty-five, or 52.24 per cent, of the patients were discharged with some evidence of weakness or paralysis. Thirty-two had paralysis of the lower extremities; one leg was involved in eighteen, and both legs were involved in fourteen patients. The three remaining paralytic patients had an involvement of the face and upper extremities. Six of the patients admitted with evidence of weakness or paralysis recovered before discharge, while one patient without paralysis on admission presented it on discharge.

There occurred one death in this series. This, of course, was among the paralytic group. The gross and histopathologic examination confirmed the diagnosis of poliomyelitis.

10. Bettman, A. G.: A Simpler Technic for Promoting Epithelization and Protecting Skin Grafts. *J. A. M. A.* 97: 1879-1881 (Dec. 19) 1931.
1. Armstrong, Charles, and Dickens, P. F.: *Pub. Health Rep.* 50: 831 (June 21) 1935.

A study of the white blood cells in fifty-two patients without any evidence of weakness or paralysis showed an average count of 10,130 cells per cubic millimeter. The lowest count was 6,160 and the highest 16,160. Twenty-seven patients with evidence of weakness or paralysis had an average cell count of 13,170. The lowest count was 8,160 and the highest was 29,040 per cubic millimeter.

COMMENT

In presenting an analysis of this small group of patients admitted to the Philadelphia Hospital for Contagious Diseases from July to November 1935 I am aware of the possibility that they may or may not represent the same type of patients seen by other physicians in this district during the same period. However, in reading the reports of other cases in Philadelphia I am rather favorably impressed with their similarity to this group. It is interesting to note that the records of the Department of Public Health of Philadelphia show that 114 cases of poliomyelitis with six deaths were reported during the year 1935. This is not a normal number for the city, for as a rule there are reported about a dozen cases annually. In this group one finds:

1. Sixty-seven patients ranging in age from 6 months to 26 years.
2. An acute onset with fever, headache, nausea, vomiting and stiffness of the neck in most of the patients.
3. An increased number of white blood cells in the spinal fluid, most of which were lymphocytes.
4. Thirty-five, or 52.24 per cent, of these patients with evidence of weakness or paralysis and thirty-two without.

I am not greatly concerned about the diagnosis of the thirty-five who showed evidence of weakness or paralysis, for I do not believe that any one will dispute the diagnosis of acute anterior poliomyelitis with paralysis in this group, but I am very much concerned with the group of thirty-two patients who were admitted during the same period who were treated in the same ward and who presented the same symptoms as the former group but who showed no evidence of weakness or paralysis on leaving the hospital.

It is natural to wonder whether one is not dealing with the same disease, some cases of which presented

paralysis while others did not. It is also natural to wonder whether one is not dealing with an entirely new disease in this group of nonparalytic patients. They might be cases of acute lymphocytic choriomeningitis, or aseptic meningitis as reported by Gunther,² or perhaps the epidemic serous meningitis as noted by Eckstein.³ Even if the foregoing diagnosis could be made in the thirty-two nonparalytic patients they certainly could likewise be called poliomyelitis without paralysis. Surely the occurrence of this condition during the summer months, the type of onset, the symptoms and signs, and the presence of paralysis in some and the absence of paralysis in others would strongly favor the diagnosis of poliomyelitis. However, it must be admitted that the absence of paralysis and the presence of a high familial tendency may be interpreted by some as sufficient evidence against such a diagnosis.

Hneleski⁴ reports twenty-three cases of acute lymphocytic meningitis in adults and Noone and his associates⁵ report thirty-seven cases of epidemic lymphocytic meningo-encephalitis in children, admitted during the same period to the Philadelphia General Hospital. In reviewing their cases it is interesting to note that the type of onset, the symptoms and signs, and the laboratory observations correspond very closely to this group of cases, except that in no instance did any of their patients show evidence of weakness or paralysis.

These authors do not believe their cases to be a mild poliomyelitis because of (1) the absence of paralysis, (2) the high familial tendency, (3) the failure to produce either choriomeningitis, poliomyelitis or encephalitis in injected guinea-pigs, mice, rabbits and monkeys, and (4) the inability of convalescent serum obtained from their patients to neutralize known virus of choriomeningitis, poliomyelitis and the St. Louis type of encephalitis.

If one pauses for a moment to reflect, one will recall that for many years the medical profession has taught that poliomyelitis without paralysis occurs more frequently than poliomyelitis with paralysis. Draper⁶

states that from 50 to 80 per cent of all cases do not go on to paralysis and he remarks: "This means that the apparent size of any given epidemic in terms of paralysis represents only from a fifth to one-half its actual extent."

2. Gunther, Allan: *Jahrb. f. Kinderh.* 128: 127-154 (July) 1930.

3. Eckstein, A.: *Klin. Wchnschr.* 10: 22 (Jan. 3) 1931.

4. Hneleski, I. S.: Unpublished Report, Philadelphia Neurologic Society, 1936.

5. Noone, E. L.; Habel, Karl, and Riggs, Helen E.: *Epidemic Lymphocytic Meningo-Encephalitis*, Am. J. Dis. Child. 52: 870 (Oct.) 1936.

6. Draper, George: *Infantile Paralysis*, New York, D. Appleton-Century Company, 1935.

Paul, Salinger and Trask⁷ show that the abortive form of poliomyelitis may be from two to five times as common as the form with paralysis. In a community studied by them 84 per cent, in another 82 per cent and in still another 77 per cent had no paralysis.

Again, if one studies the 1916 and 1932 epidemics in Philadelphia,⁸ the 1916 and 1931 epidemics in New York City,⁹ the 1930 and 1934 epidemics in California¹⁰ and the 1935 epidemic in the South¹¹ one cannot help but be impressed by the growing tendency for poliomyelitis (1) to affect the older age groups, (2) to have a lower attack rate, (3) to cause fewer cases of residual paralysis and (4) to show a gradual decrease in the death rate.

A high familial tendency was not a prominent feature in my cases. In this group of sixty-seven patients only eight cases occurred in three families. In the 1931 epidemic in New York City, 3,999 families were affected. Of this number, 3,901, or 97.5 per cent, had one case per family and ninety-eight families, or 2.5 per cent, had more than one case. My percentage figures compare most favorably with these.

The failure to produce disease from nasal washings, spinal fluid and other tissues and the inability to demonstrate the presence of antiviral substances in convalescent serum of patients, even for a known or mixed type of virus, is only presumptive evidence against a disease and is not absolute. Kolmer¹² states that from 12.1 to 63.2 per cent (average 34.9 per cent) of those who have had an attack of poliomyelitis may not have antiviral substances in their blood.

Therefore, if one is to make the clinical diagnosis of acute lymphocytic meningitis, acute lymphocytic choriomeningitis, acute epidemic meningo-encephalitis in the type of cases herein reported, one must deny the existence of poliomyelitis without paralysis, and no case could be safely diagnosed poliomyelitis unless there was evidence of weakness or paralysis. It is true that in the laboratory a virus which behaves differently from that of poliomyelitis has been isolated by many investigators, but this is of no help to the physician in practice. From the public health point of view it is much safer and wiser, at the present time, to handle such patients as having acute anterior poliomyelitis without paralysis.

In view of the facts presented, I believe that Philadelphia, like other districts, experienced a mild or an atypical form of poliomyelitis in 1935.

A Seeming Paradox.—It has been a seeming paradox that the medical profession has so consistently endeavored to make of the world a place where there is a constantly lessening need for the medical man. He is, indeed, already feeling the effect of these efforts, and as he becomes more and more a servant of the public health, and less and less a prescriber for individual ills, he philosophically accepts and humanely welcomes this outcome of medical discoveries which the experimental method has already given and will increasingly continue to give.—Cushing, Harvey: *Consecratio Medici and Other Papers*, Boston, Little, Brown & Co., 1928.

THE ADDIS COUNT IN CHILDREN

FOLLOWING CLINICAL RECOVERY FROM POST-
INFECTIOUS NEPHRITIS

H. H. BOYLE, M.D.

C. A. ALDRICH, M.D.; ALBERT FRANK, M.D.

AND

SYDNEY BOROWSKY, M.D.

CHICAGO

A method for the quantitative estimation of the constituents of urinary sediment was described by Addis¹ in 1925. He advanced the idea that the type of renal pathology might be predicted from study of the sediment. The following year he² published what he considered to be normal figures for the various constituents, particularly red blood cells, leukocytes and epithelial cells, and casts. Since that time Goldring³ has made studies of the sediment of clinically well adults and of adults with nephritis, rheumatic heart disease, subacute bacterial endocarditis and pneumonia. His averages for normal adults were higher than those of Addis. Naeraa⁴ has reported figures for well adults higher than those of Addis and lower than those of Goldring. He also made the interesting observation that the number of red blood cells increases with the age of the individual.

The first work with children in this field was reported by Rew and Butler,⁵ who studied the urinary sediment from three groups of children: sixteen children with no known kidney disease or recent infection of any kind, sixteen children during or just subsequent to acute infections, five children with nephritis, and one with nephrosis. The latter determinations were made during active stages of the kidney disease. Lyttle⁶ studied the sediment of a group of normal children and set up normal standards for the various constituents; he⁷ also made studies of the sediment of children with scarlet fever. Palacios and Otero⁸ have also made determinations of the urinary sediments of normal children, and the results obtained agree in general with those of the other authors; their red blood cell counts were slightly higher. We have not found any records of determinations made on children who have clinically recovered from acute postinfectious hemorrhagic nephritis.

In our clinic we have been particularly interested in both the immediate and the ultimate prognosis of acute postinfectious hemorrhagic nephritis in children. We have used a follow-up system in our dispensary to observe these children personally once or twice a year after recovery until they become too old for our clinic. More recently we have made provisions to follow them on through adolescence and the "teen" age. We have been able to show that after these children recover from their nephritis they remain completely well and are free from kidney disease as far as we can determine by the usual clinical and laboratory procedures. It occurred

to us that a study of the urinary sediment of these children might be of benefit in assisting us to determine more definitely the condition of their kidneys.

MATERIAL AND TECHNIC

We have observed approximately 250 children who have had acute postinfectious hemorrhagic nephritis and have made a clinical recovery. Twenty-five of these, or about 10 per cent, were selected for this study. We attempted to select a representative cross section of the total group for our study, although in general the children observed suffered from more severe and more prolonged illnesses than did the average of the entire group. Table 1 includes a complete list of the children, with a brief summary of the clinical history and course of illness. In this table is also noted the length of time between the onset of nephritis and the Addis count; this varies from one-half to eight years.

Two classes of patients are generously included in this study: those with acute cerebral manifestations and those with a persistent albuminuria following an otherwise complete recovery. Ten of the twenty-five children had enough evidence of cerebral involvement, such as hypertension, twitchings, convulsions or coma, to cause special notations to be made on their records. This is a higher percentage than that in the group as a whole. Also, four children in this group had albuminuria which persisted longer than three months, while we have had only eight in the entire group who have behaved in this manner.

All of the patients but one (patient 8) had a definite history of an acute febrile infection preceding the nephritis. In this one case it was not possible to get a history of the nature of the preceding infection; he was stuporous on admission and the blood pressure was high. He made a rapid recovery, following administration of magnesium sulfate. There were nineteen boys and six girls. The preponderance of the former is explained by the fact that some of our specimens had to be collected at home and that it is easier under home conditions to obtain urine free from extrarenal white and epithelial cells from boys.

Two of the boys had had two distinct attacks of nephritis, each followed by complete recovery. One boy (patient 4) passed less than 2 ounces of urine a day for two weeks, and then, following diuresis, made a complete recovery.

The methods used for collecting specimens and making the counts were those described by Addis, as modified by Lyttle for children. Fluids are severely restricted during the day preceding the collection of urine; then all the urine passed between 7 p. m. and 7 a. m. is collected in one container. A definite quantity of the urine is centrifugated at a given speed for a given length of time and a quantitative estimation of the formed elements is made in a counting chamber. From this figure the total number of cells and casts in the twelve hour specimen is calculated. We too have observed the impracticability of restricting fluids severely in children, but all specimens reported here were acid in reaction and of specific gravity 1.018 or higher. Total protein determinations were not made.

Counts were made on children from other wards in order to familiarize ourselves with the technic. Counts were also made on children with active nephritis and nephrosis and in all of these the expected high figures were obtained. These two groups of children thus served as controls.

Because of lack of space, seven of the twenty-five children could not be hospitalized. In each of these

TABLE 1.—Clinical History of Twenty-Five Patients

Case No.	Summary of History* and Examination	Interval Between Onset of Nephritis and Addis Count	
		Addis Count	Addis Count
1	Otitis media; questionable history of scarlet fever; hemolytic streptococcus abscess over clavicle; very ill; uneventful recovery	5 yrs.	R: 0 W&E: 64,444 C: 0
2	Otitis media; marked hypertension; function moderately decreased; uneventful recovery following mastoidectomy	1 yr.	R: 60,000 W&E: 600,000 C: 0
3	Scarlet fever; admitted with acute cerebral complications; convulsion and marked hypertension; elevation of blood chemistry figures; rapid recovery	4 yrs.	R: 0 W&E: 0 C: 0
4	Streptococcal throat infection followed by cervical adenitis; moderate edema with almost complete suppression of urine for two weeks; rapid recovery	2 yrs.	R: 0 W&E: 450,000 C: 0
5	Scarlet fever; mild nephritis; albuminuria persisted for three months	3 yrs.	R: 0 W&E: 302,500 C: 36,661

* All patients had albuminuria, hematuria and cylindruria in the acute stage of their nephritis.

Explanation of symbols used in table: R, red blood cells; W&E, white and epithelial cells; C, casts.

instances the mother was given detailed written instructions and the specimens were obtained at home. These proved as satisfactory as those obtained in the hospital with the exception of specimens collected from girls. Several of the latter were rejected because of excess of epithelial and white blood cells. Of the seven home specimens, only one was from a girl.

RESULTS

The results of the cell and cast determinations for each child are shown in table 1. With the exception of one girl (patient 13) the figures correspond well with those established by Lyttle for normal children. This girl had a moderately severe case of acute postinfectious hemorrhagic nephritis about one year previous to this study and made a complete clinical recovery. After she was discharged from the hospital she was observed in the dispensary with normal urine and negative observations. Her first Addis count was abnormally high for all formed elements and she was readmitted to the hospital for a second count about two weeks later. The results of the two counts were practically the same. We did not feel that the manifestations were due to a chronic or latent nephritis and she was admitted to the general pediatric service for further study and diagnosis. Intravenous pyelograms revealed a hydronephrosis on one side and a diagnosis was made by the urologist of a pyogenic or tuberculous infection of the kidney. She is to be observed carefully and the ultimate outcome will be reported.

Table 2 compares the limits for cells and casts established by Addis for normal adults, Lyttle for normal children, and our group of postnephritic children; the averages for these groups also are given. It will be noted that the average number of red cells, not including the one exception mentioned, is 19,817, as compared to Lyttle's average of 15,181 for normal children. For white and epithelial cells our average is 337,707, as compared to his normal of 322,184. The average number of casts is 3,410; Lyttle's average was 1,085. Our percentage of zero cast counts and zero red blood cell counts compares very favorably with those of Lyttle for normal children: 64 per cent for the former in our series as compared to his 73 per cent, and 72 per cent for the latter as compared to his 67 per cent. However,

no correlation between the number of casts and that of red blood cells. Some specimens with no blood cells have casts and some with no casts have blood cells.

SUMMARY AND CONCLUSIONS

1. Quantitative determinations were made of the constituents of the urinary sediment obtained by the method of Addis from twenty-five children who had clinically recovered from acute postinfectious hemorrhagic nephritis for periods of from one-half to eight years.
2. With the exception of one girl, the figures obtained correspond very closely to those obtained on normal children. This one girl, who had an abnormally high count, was found to have a hydronephrosis.
3. Except in this one case, pathologic sediments were not found when ordinary clinical and laboratory procedures gave normal reactions.
4. We feel that our results furnish further evidence toward the view that children who have clinically recovered from acute postinfectious hemorrhagic nephritis do not have subacute or latent nephritis. In this work clinical recovery implies absence of all known symptoms and signs of nephritis, as well as completely negative urinalyses as routinely conducted.

APPENDICITIS

A STATISTICAL SURVEY OF 10,000 CONSECUTIVE CASES AT PROVIDENCE HOSPITAL

JAMES E. DAVIS, M.D.
PAUL H. MUSKE, M.D.
PHILLIP L. MULLIGAN, M.D.
AND
JULIUS GUTOV, M.D.
DETROIT

The data collected for this survey are based on all the clinical cases of appendicitis registered in Providence Hospital, Detroit, during the decade January 1925 to May 1935 and represent the treatment of 10,000 cases by approximately twenty-five different surgeons. The statistics are the result of critical analyses of all appendix cases, the combined information of clinical history and histopathologic reports. More than 98 per cent of all the appendixes were examined histopathologically by the senior author. In cases in which disagreement arose between the clinical and the tissue diagnosis, the sections were reviewed or additional sections were cut and examined. The pathologist's diagnosis was then adopted in classifying the case, but in some instances both the clinical and the histopathologic information was relied on for this purpose.

The clinical diagnoses of acute appendicitis corresponded with the pathologic diagnoses in 85.6 per cent of the cases.

One of the primary purposes in making this survey was to determine accurately the mortality rate in cases of appendicitis in this hospital. There were 379 deaths recorded in the 10,000 cases reviewed for the decade, giving an uncorrected death rate of 3.79 per cent for all cases with a clinical diagnosis of appendicitis.

Of the deaths indicated in table 1, ninety-three occurred in the chronic appendicitis group, constituting 1.3 per cent of all chronic cases and 24.5 per cent of all deaths; 257 deaths occurred in the acute appendicitis group, constituting 9.92 per cent of the acute cases and 67.8 per cent of the total deaths; twenty-nine deaths occurred in an unclassified group of cases in

TABLE 2.—Limits for Cells and Casts

	Adults (Addis)	Normal Children (Lyttle)	Postnephritic Children
Casts			
Range.....	0 to 4,270	0 to 12,916	0 to 18,611
Average.....	1,040	1,085 ± 123	3,401
Red blood cells			
Range.....	0 to 425,500	0 to 129,000	0 to 114,000
Average.....	65,750	15,181 ± 1,400	19,817
Epithelial and white blood cells			
Range.....	32,400 to 1,835,000	9,000 to 2,822,000	0 to 990,000
Average.....	322,500	322,184 ± 23,500	337,706

in our patients when casts were found they were present in slightly greater number; his highest cast count was 13,000 and ours was 18,600. When the extremely large factor used in calculations is considered, this is not a great difference and may be considered to be within the limits of ordinary error in counting. A difference of one cell per square in the chamber makes a difference of 10,000 in the total specimen.

Naeraa⁴ made an observation in normal adults which we noted in our group of children: there is apparently

which insufficient clinical data were recorded or no operation was performed. These twenty-nine deaths constituted 11.51 per cent of the unclassified group of cases and 7.7 per cent of the total deaths. This last group of cases includes justifiable exemptions from the total reported because appendectomy operations were not performed or deaths resulted from causes other than the removal of the appendixes.

THE INFLUENCE OF SEX

Sex was recorded in 9,382 cases; 6,076 were females and 3,306 were males.

The factors explaining the high incidence in females were the predominance of female admissions to the hospital and the frequency of removal of the appendix incidentally to other operative procedures in the female. In eighty-four cases normal appendixes were removed as a prophylactic procedure during female pelvic operations. Deaths in females constituted 45.3 per cent of the total fatalities, and about 80 per cent of chronic cases occurred in the female patients.

The simple acute, suppurative, gangrenous and ruptured forms of appendicitis were encountered much more frequently in males, and this is responsible for the high mortality rate in this sex.

There were 169 deaths among the 6,076 female patients, giving a mortality rate of 2.8 per cent; 201 deaths occurred among the 3,306 male patients, giving a mortality rate of 6.1 per cent.

AGE GROUPS AND MORTALITY

The age of patients was recorded in 7,434 cases, the youngest being 10 months of age and the oldest over 80 years. These cases, when arranged in age groups, show the following interesting percentages:

Children under 5 years of age numbered eighty-two, or 1.1 per cent of the total of 7,434 cases of appendicitis; the deaths in this group numbered fifteen, or a mortality rate of 18.3 per cent.

Children from 5 to 10 years of age numbered 320, or 4.3 per cent of the total group; the deaths numbered twenty-eight, or a mortality rate of 8.8 per cent.

Individuals between 10 and 40 years of age numbered 6,147, or 82.5 per cent of the 7,434 cases; the mortality rate in this group was 2.86 per cent.

Cases in the age group of 40 to 50 years numbered 631, or 8.5 per cent of the total group, with a mortality rate of 7.8 per cent.

Cases in the age group of 50 to 60 years numbered 201, or 2.7 per cent of the total; the deaths numbered thirty-seven, or a mortality rate of 18.4 per cent. This rate will be observed as almost identical with that encountered in the first five year period.

The cases of appendicitis in the age group over 60 years numbered thirty-three, or 0.7 per cent of the total; the mortality rate in this group was 34 per cent, being the highest obtained for any age.

It is evident that the age groups 1 to 10 years and 50 to 90 years contributed 79.5 per cent of the total mortality. Extremes of life, therefore, produce the fewest number of cases but yield the highest mortality rates.

The greatest incidence of appendicitis was in the 20 to 30 year period, or 3,626 cases, with seventy-one deaths in this group, a mortality rate of 2.3 per cent. This is a distinct contrast with the statement of H. M. Beebe that the greatest risk appears during this life period.

There were 402 cases in children under 10 years of age, 75.4 per cent of which were classified as acute.

Moreover, 10.3 per cent of all ruptured appendixes were found in this small age group. The high mortality in young children is due to the high incidence of appendicitis in the acute form in this group, and especially the occurrence of rupture.

TEMPERATURE RELATIONSHIPS

In 85.1 per cent of all cases there was an admission temperature of between 97 and 100 F.

In 40.3 per cent of the cases in which appendixes were ruptured the admission temperature was over 100 F.

TABLE 1.—*Classification of Cases of Appendicitis, Providence Hospital, 1925-1935*

Type of Case	No. of Cases	Percent- age of Cases	No. of Deaths	Uncorrected Death Rate, Percentage*
Chronic.....	7,147	71.47	93	1.30
Acute.....	2,590	25.90	237	9.92
Simple acute.....	1,430	14.30	94	6.57
Acute gangrenous.....	760	7.60	61	8.02
Acute ruptured.....	400	4.00	102	25.50
".....	2	0.02	0	0
".....	9	0.09	0	0
".....	232	2.52	29	11.51
Totals.....	10,000	100.00	379	3.79
Corrected death rate.....				2.92

* All deaths based on clinical diagnosis of appendicitis.

† Insufficient clinical data or no operation performed.

In only 4.8 per cent of all the chronic cases was the admission temperature over 100 F.

In 68.2 per cent of cases terminating fatally the temperature was between 102 and 104 F. This high temperature was reached within five days after operation in 83.7 per cent of the cases, and in the simple acute, gangrenous and ruptured forms it was reached within two days after operation.

RELATIONSHIP OF TYPE OF APPENDICITIS TO PERIOD OF CONVALESCENCE

Only 5.4 per cent of the cases of chronic appendicitis required more than twenty days for recovery. Of the acute forms, 12.5 per cent required more than twenty days for recovery, and 31.2 per cent of the ruptured appendix cases required more than twenty days.

From the standpoint of mortality, the first week after operation was the most dangerous period, 74.1 per cent of deaths having occurred during that time.

RELATION OF BLOOD PICTURE TO APPENDICITIS

Blood counts were recorded in 6,601 cases; of these, sixty-five cases showed a leukopenia and fifty-nine of the sixty-five cases were in the chronic group, four were in the simple acute, one was gangrenous and one was ruptured. Five deaths, or 7.7 per cent, occurred in this leukopenic group.

In 3,086 cases the leukocytes numbered from 5,000 to 10,000; 2,776 of these were classed as chronic appendicitis, 246 as simple acute, thirty-three as gangrenous, and thirty-one as ruptured. Fifty-nine deaths occurred, a mortality of 1.6 per cent.

In 2,265 cases there was a leukocytosis of from 10,000 to 15,000; 1,623 of these were classed as chronic, 490 as simple acute, 104 as gangrenous, forty-seven as ruptured, and one as a tuberculous appendix. Forty-three deaths in this group gave a mortality of 1.9 per cent.

In 1,031 cases a leukocytosis of from 15,000 to 25,000 occurred; 378 of these were classed as chronic, 372 were simple acute, 186 gangrenous, ninety-four ruptured, and one was a carcinoid appendix. There were 124 deaths, or a mortality of 12 per cent.

air. A ring of anthers containing millions of pollen grains appears at the base of the head when flowering begins.³ The grains are hung in such a fashion that the lightest jar shakes them, thereby floating them out into the air. Pollination begins about May 15 and continues until early September, only small amounts being disseminated after July 1.

English plantain.

Common or broad leaved plantain is not nearly so abundant in the United States as is the English variety. It grows only on low, moist land. It does not bloom as early as the English variety but continues throughout the summer.

LITERATURE

Scheppegrell⁴ listed plantain among the minor group of plants causing hay fever. Walker⁵ considered uncomplicated plantain hay fever a rarity, having seen only two such cases in New England. Thommen⁶ has seen only four plantain cases in seven years and therefore believes that it is one of the minor causes of hay fever. The only attempt to establish the incidence of this type of hay fever was Bernton's⁷ study of 116 cases of hay fever. The subcutaneous test was used as a criterion for clinical sensitivity; that is, from 3 to 20 pollen units was injected subcutaneously and read as positive if an area of erythema and edema appeared within twelve to twenty-four hours. He believed that the subcutaneous test corresponded more closely with mucous membrane sensitivity than either the intracutaneous or the cutaneous test. Using the subcutaneous test and the pollen of English plantain, he found five out of 116 patients sensitive, an incidence of 4.3 per cent. Four of these five cases were from a group of twenty-four patients having vernal hay fever, an incidence of 16.6 per cent.

PROCEDURE

In order to ascertain the incidence of plantain hay fever it was decided to review all the hay fever cases that had come under observation at the Allergy Clinic of Temple University Hospital. The relative frequency of positive skin reactions in both the vernal and the fall types of hay fever was noted. All patients showing moderately positive skin reactions to plantain pollen were tested by the ophthalmic⁸ and nasal routes,⁹ the latter being our chief criterion for clinical sensitivity. These tests were especially valuable in those cases in which the clinical history was indefinite or coincided with the pollinating period of the grasses. Passive transfer tests after the method of Prausnitz-Küstner were performed on all clinically sensitive patients to determine the presence of reagins. Neutralization and cross-testing both in the passively sensitized skin sites and in the test tube were carried out to determine the antigenic relationship, if any, between English and common plantain.

RESULTS

Of the 213 cases reviewed, thirty-three were incompletely studied, leaving 180 cases that were considered sufficiently satisfactory to be included in the present report. These cases may be divided into three groups: first, those giving a history of seasonal fall hay fever, of which there were 110; second, those giving a history of seasonal spring hay fever, of which there were forty; and, finally, those giving a history of both spring and fall hay fever, of which there were thirty. The accompanying table will show that the greatest percentage of

Common plantain.

positive skin reactions occurred in the spring and fall or combined group 46.6 per cent, next in the spring group 42.5 per cent, and least of all in the fall group 18.1 per cent. Positive skin reactions occurred in 28.3 per cent of the 180 patients studied. Dry pollen ophthalmic and

9. Efron, B. G., and Penfound, W. T.: Nasal Test with Dry Pollen in Diagnosis of Seasonal Hay Fever, J. Allergy 2: 43-47 (Nov.) 1930.

nasal tests were done in 105 of the 180 cases, or 58.3 per cent of the group. Care was taken to insure the completion of these tests in every case that yielded a positive skin reaction, so that we would not overlook an occasional patient who was clinically sensitive. It will be seen that not one case of plantain hay fever was found in those patients who had a history of seasonal autumnal hay fever only. On the other hand, seven of the forty patients with spring hay fever exhibited clinical

Results of Tests

Total.....	180	51 or 28.3%	105 or 58.3%	14 or 7.7%

cal sensitivity to plantain pollen, an incidence of 17.5 per cent, and seven of the thirty, or 23.3 per cent of the spring and fall or combined type, showed clinical sensitivity. In other words, plantain pollen was an etiologic factor in 20 per cent of the spring variety of hay fever and in 7.7 per cent of all types of hay fever.

Passive transfer studies with the serums of sensitive patients showed that reagins for both common and English plantain were present in all fourteen cases. When passively sensitized sites were exhausted with one of the plantains they failed to react to the other plantain extract, in each one of the eight cases studied. Likewise, when reagin-containing serums were neutralized in vitro with an equal amount of English plantain pollen (containing 0.42 mg. of nitrogen per cubic centimeter) and allowed to stand for twenty-four hours before passive transfer sites were prepared, they also failed to react to common plantain after a lapse of from twenty-four to forty-eight hours. The same was also true when each of the eight serums was neutralized with common plantain and tested with English plantain. These results indicate that the English and common plantain pollen contain a common antigenic factor. That the plantain antigen is in no way related to either timothy or ragweed was shown by our ability to obtain positive reactions to plantain after the timothy and ragweed reagins in the serums had been neutralized with timothy or ragweed pollen extract. This contention is further borne out by the fact that after neutralization with one of the plantains either by exhaustion or in vitro we were still able to obtain a positive reaction to either timothy or ragweed pollen extract.

COMMENT

One of the previous difficulties in establishing a diagnosis of plantain hay fever has been the inability to differentiate it from that of timothy or other grasses whose period of pollination coincides with that of plantain. The dry pollen ophthalmic and nasal tests provide additional methods of establishing accurate etiologic diagnoses in hay fever patients. These tests aid in detecting the presence or absence of clinical sensitivity. They manifest their greatest usefulness in distinguishing the clinical importance of those pollens in which the pollinating periods coincide.

Plantain is considered a weed by most authorities and yet it makes its appearance at the same time as the grasses. It is not at all surprising, therefore, that all our cases of clinical sensitivity to plantain pollen

occurred in patients giving histories of spring hay fever. It is likewise interesting to note that we encountered five cases of uncomplicated plantain pollen hay fever, a condition considered rather uncommon by most observers.

Unsuccessful results in the treatment of spring hay fever frequently lie in the incorrect etiologic diagnosis and the subsequent error of not combining plantain pollen with the grass pollens used. That this is a requirement for good results in the treatment of combined grass and plantain hay fever is proved by the fact that no antigenic relationship exists among the pollens of plantain, the grasses and the weeds. We encountered several failures in the treatment of spring hay fever in which successful results followed the inclusion of plantain extract along with the grass pollen extract. We were gratified by the excellent results obtained by hyposensitization in this group of patients.

CONCLUSIONS

1. In a group of 180 thoroughly studied hay fever patients we encountered fourteen cases of plantain sensitivity, an incidence of 7.7 per cent.
2. In a group of seventy patients with spring hay fever, plantain pollen was found to be an etiologic factor in 20 per cent.
3. Antigenically the pollens of English and common plantain are identical.
4. The pollens of timothy and of ragweed bear no relation to those of plantain.
5. Treatment by hyposensitization yielded excellent results in all cases.
6. The use of the dry pollen nasal test is an invaluable aid in arriving at a correct diagnosis of plantain hay fever, especially when a grass hay fever coexists.

Clinical Notes, Suggestions and
New Instruments

FAMILIAL CONGENITAL HEART DISEASE
PATENT DUCTUS ARTERIOSUS IN SISTERS
DAVID B. SNELLING, M.D., MONTGOMERY, ALA.

Although patent ductus arteriosus or persistent ductus botalli is one of the more common forms of congenital heart disease, its occurrence in members of the same family is a rarity and hence seems worthy of reporting. The cases to be reported here were discovered during the routine examination of one of the sisters. When told of the condition and reassured about it, she stated that she was aware of the situation, that it had never perturbed her, and that her older sister had the same condition and had told her it was nothing to worry about. Accordingly the older sister was requested to report for examination.

There was no family history of cardiac disease. Neither the father nor the mother or a living brother exhibited a heart murmur.

REPORT OF CASES

CASE 1.—An unmarried white student nurse, aged 20, had no complaints. She was a full term child with a normal delivery. She was not a "blue baby." She had had diphtheria, whooping cough and measles in childhood without complications. Three years before she came under observation she had an appendectomy for an acute attack of appendicitis. Recovery was uneventful. She stated that since childhood she had noted dyspnea and palpitation on exertion, which she thought might possibly be a little more prominent than in other normal girls of her age, but she was rather vague about this. At 6 years of age a preschool examination revealed a heart murmur and she was advised to go to bed for a year. This advice was disregarded and she has led practically a normal life since.

The patient was of rather asthenic habitus. Her height was 5 feet 5½ inches (167 cm.) and weight 115 pounds (52 Kg.). There was no cyanosis of the face or extremities or clubbing of the fingers. The positive physical signs were confined to the heart. Examination of this organ revealed a very faint systolic thrill at the base. The left border of dulness and the apex impulse were 8.5 cm. to the left of the midsternal line in the fifth interspace just inside the midclavicular line. The right border of dulness was at the right sternal margin. There was no widening of the retromanubrial dulness. There was a continuous machinery-like murmur with systolic accentuation heard all over the precordium but loudest in the second left interspace, where it was so loud that it obscured the normal first and second sounds. At the apex it was relatively quite faint. It was faintly transmitted all over the chest anteriorly as well as to the left axilla. It was heard with still more difficulty posteriorly over both interscapular regions and at the left base. It was not heard above the clavicles. The radial pulses were equal, the rhythm was regular, the rate was 78 and the vessel walls were not remarkable. The blood pressure was 100 systolic, 60 diastolic. The lungs were clear and there were no other signs of decompensation.

The Kahn and Wassermann reactions were negative. Erythrocytes numbered 4,300,000, leukocytes 7,300. Hemoglobin was 84 per cent. Blood smear and differential count were normal. The urine was normal. The electrocardiogram was normal in four leads, there being no right axis deviation. A teleroentgenogram showed the width of the heart shadow to be within the limits of normal, the greatest transverse diameter of the thoracic cage being 28.5 cm. and that of the heart silhouette 13 cm. The pulmonary conus was not prominent.

CASE 2.—A graduate nurse, aged 28, had no complaints. She was born at term; the mother was jaundiced at delivery. Labor was prolonged but was otherwise normal. The patient was not a "blue baby." Generally her health had been good. She had typhoid at 2 years of age and catarrhal jaundice at 8, and she had been operated on for acute appendicitis when she was 12. She never had rheumatic fever, scarlet fever or diphtheria. She was subject to periodic headaches. There had been no signs or symptoms of cardiac decompensation. She stated that since childhood she had always had the "feeling of a little stream of water about the size of the stream from a hypo needle" in the region of the second left intercostal space. This had varied somewhat in intensity but had never been entirely absent. She had thought this normal until she was 14 years of age, when she was confined to bed for a few days because of an "upset stomach." The heart murmur was discovered then for the first time. Although prolonged rest in bed was recommended, she continued to lead a fairly normal existence. Her history otherwise is negative.

The patient was undernourished, her height was 5 feet 4½ inches (163 cm.) and her weight 96 pounds (43.5 Kg.). There was no cyanosis of the face or extremities and no clubbing of the fingers. The neck veins were not distended. The positive signs were confined to the heart and in this respect she was almost a "carbon copy" of her sister. There was a faint continuous thrill with systolic accentuation to the left of the sternum in the region of the first and second ribs. The left border of dulness and apex impulse were 7.5 cm. to the left of the midsternal line in the fifth interspace. There was no widening of the retromanubrial dulness. There was a continuous machinery-like murmur with systolic accentuation heard all over the precordium but loudest in the first and second interspaces to the left of the sternum; there it was very loud. The murmur was relatively quite faint but audible at the apex. The normal first and second heart sounds could be heard only at the apex. At the base they were obscured by the murmur. The systolic portion of the murmur was transmitted to all parts of the chest, but anteriorly in the left side of the chest and in the left axilla both systolic and diastolic portions were heard. It was not transmitted above the clavicles. It will be seen that the only difference in the signs presented on examination of the two hearts is the extent to which the diastolic portions of the thrill and murmur are transmitted. The radial pulses were equal, the rhythm regular and the rate 80 per minute. The blood pressure was 106 systolic, 60 diastolic. The lungs were clear, and examination revealed no other abnormalities.

The Kahn and Wassermann reactions were negative. The blood count was normal except for slight secondary anemia.

The electrocardiogram was normal in four leads, there being no right axis deviation. A teleroentgenogram showed the width of the heart shadow to be at the upper limit of normal, the greatest transverse diameter of the thoracic cage being 21 cm. and that of the heart silhouette 10.5 cm. The pulmonary conus was not prominent.

COMMENT

The occurrence of such a congenital anomaly in members of the same family is of particular interest in view of the paucity of reports in the literature of such occurrences. However, the familial incidence of congenital abnormality of the heart was noted over a century ago and at least one such observation was described some forty years before the publication of the first book on congenital heart disease by Peacock¹ in 1858. Tedesco² in reporting two cases of familial congenital heart disease in sisters, one with an interventricular septal defect and pulmonic stenosis, the other with an interventricular septal defect and mitral stenosis, gave a concise summary of the literature on this topic:

"The first observation [on record] is that of Cooper and Englenot (1818), who speak of twelve brothers, most of whom presented from birth indubitable signs of heart disease. Two of these died at a rather advanced age, and necropsy revealed a definite stenosis of the isthmus of the aorta, persistence of the ductus botalli and perforation of the superior part of the interventricular septum, while the pulmonary artery, was derived simultaneously from the two ventricles, straddling, as it were, the abnormal communication. Friedberg (1844) speaks of three babies belonging to the same family affected with congenital cyanosis. Orth (1880) cites the observation of two babies of the same father but of different mothers, who presented congenital malformation of the heart. Potocki (1886) was able to observe different members of two generations of the same family who presented the same cardiac malformation. De La Camp (1903) noted in two sisters and four brothers congenital malformations of the heart, identical in every respect. Saller (1905) cites the case of a family in which five babies of the first marriage were affected with congenital cyanosis, while the mother, having married the second time, brought forth normal children. Interesting also is the observation of Burwinkel: a man 54 years of age, cyanotic from birth, as were his mother and grandmother, who, having married, had three children, two of whom were cyanotic due to congenital heart disease. Hess and Pearce (1917) refer to three cases of congenital cyanosis in three babies of the same family. Debré (1891) writes of a mother and child, both of whom were affected with *maladie de Roger*. Appert and Cambessedes (1930) mention a mother and two children (of different marriages), all three of whom were affected with congenital cardiac malformation, and recently Robbioni calls attention to three brothers with congenital cyanosis."

The most recently published report is that of Ellis.³ Two sisters, aged 9 and 5 respectively, presented signs which are to be interpreted as patent ductus arteriosus. Both had loud systolic murmurs at the base with prominence of the pulmonary conus in the roentgenogram. Dr. Carter Smith⁴ reports two brothers, aged 4 and 6, with congenital deformity of the pulmonic valve, noncommunicating.

In both of the cases reported here the diagnosis was obvious because of the characteristic murmur which they exhibited, although neither presented the important confirmatory sign, prominence of the pulmonary conus in the roentgenogram. There is of course the possibility that one or more other malformations may accompany the patent ductus in both instances, but on the available evidence this cannot be certainly the case. It is probable that the degree of patency is comparable in the two and that the abnormal communication between the aorta and the pulmonary artery is relatively small. This is attested by the loudness of the murmur and the absence of any considerable dilatation of the pulmonary conus. The latter condition is due to the increased pressure in the pulmonary artery and, when it occurs, is the result of a relatively free or large communication between this vessel and the aorta.

3. Ellis, R. W. B.: *Congenital Morbus Cordis in Two Sisters*, *Proc. Roy. Soc. Med.* 26:511-512 (March) 1933.

4. Smith, Carter: Personal communication to the author.

It is evident that the defect has caused neither of the patients any considerable disability. Although both are somewhat underweight, and this is probably incidental, their health has not been otherwise impaired. In this connection, witness the major operation which both underwent without complications. Contrary to the advice of their physicians, they have led practically normal lives since first the murmurs were discovered. They are probably fortunate in this respect in that they have thereby been spared lives of needless invalidism.

In view of the definite hazard of a superimposed subacute bacterial endocarditis on the existing lesion and of pulmonary tuberculosis, it is extremely important that the general health and resistance of these patients be built up and maintained at the highest possible point by the usual hygienic and dietary measures.

1103 Bell Building.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

HOGAN BREVATHERM SHORT WAVE DIATHERMY UNIT, CLINIC MODEL 8820 (TWO-TUBE) ACCEPTABLE

Manufacturer: McIntosh Electrical Corporation, Chicago.

This unit is recommended for medical and surgical diathermy. It is essentially the same as the Hogan Brevatherm Short Wave Diathermy Unit, Model 8800 (Two-Tube), the acceptance of which was recorded in *THE JOURNAL*, May 9, 1936, page 1660. The firm states that the difference between Model 8800 and Model 8820, the unit under consideration, is a change in the circuit as well as the wavelength, Model 8820 employing an ultra-audion circuit with a wavelength of 18 meters.

Model 8820 calls for the upper cabinet housing the mechanism and the standard accessories; the firm states that the model number is modified to 8821 when the mobile subcabinet is included.

The apparatus is mounted in a wooden cabinet and all working parts are mounted on a chassis, readily removable from the cabinet for inspection and repairs. The oscillator or tank coil is insulated from the wooden chassis by means of ceramic stand-off insulators. The circuit employed is a variation of the Colpitts group.

Inductance of the patient's circuit is inductively coupled to the oscillator or tank coil. Sufficiently loose coupling is employed to prevent overloading of the tubes.

Frequency of the current is about 16.6 megacycles per second, which corresponds to a wavelength of approximately 18 meters. Under maximum load, the power input is about 850 watts.

The firm was asked to submit evidence from a reliable investigator to substantiate the claims made for the unit. Using

human subjects, the heating effect of the tissues in the thigh was observed. Both cuff and cable electrodes were used. Nine men, ranging in age from 23 to 31 years, were obtained for the experiments. Temperature measurements were observed by hypodermic needle thermocouples, manufactured by the Leeds and Northrup Company, and the Portable Precision Potentiometer made by the same company. The skin temperatures were observed on two disk thermocouples made especially for the work. All these thermocouples were checked against a Bureau of Standards thermometer, reading to one-tenth degree Centigrade.

Hypodermic needle electrodes were inserted before turning on the current and immediately after shutting it off. In all tests the current was turned on for exactly twenty minutes. One needle was inserted from 1½ inches to 2 inches, depend-

ing on the thickness of the thigh; the other needle was inserted subcutaneously, just beneath the skin structure. The cable was wrapped around the thigh four and three-fourths times. First, however, two towels were wrapped around the thigh, and then an extra towel was folded and placed on the superior surface of the thigh, on which the cable rested. Cuff electrodes of size 2

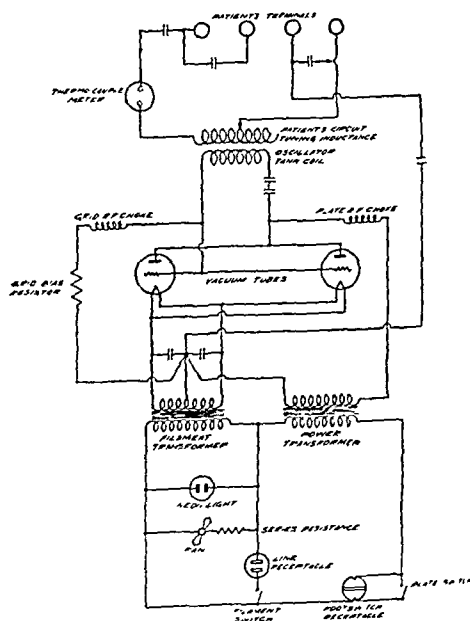

Averages of Nine Observations

	Skin Temperature Under Electrode		Deep Muscular Temperature		Oral Temperature	
	Initial	Final	Initial	Final	Initial	Final
(cuffs)	93.5	101.3	95.6	103.2	98.7	98.7
(cable)	87.5	95.2	98.6	105.9	98.9	99.1

inches wide, one-half inch thick and 24 inches long were wrapped around the thigh, one distal to the hip and the other proximal to the knee, with two towels next to the skin and a one-half inch flannel between the towels and the electrodes.

Results indicate that the temperature rise with the aforementioned method of application is considerably above what can be expected in the application of conventional diathermy—with a metal electrode on the medial aspect of the thigh and another metal electrode on the lateral aspect—the method of application that has been adopted as a minimum standard of acceptance.¹

Temperature rise of the plate power transformer and the filament transformer after the machine had been operated at

Schematic Diagram of Circuit.

full load for two hours came within the limits of safety prescribed by the Council. The shipping weight of the apparatus is about 77 pounds. Burns may be produced but may be avoided by ordinary precaution. Their likelihood to occur is less than with conventional diathermy, employing metal electrodes.

The machine was used in a clinic acceptable to the Council and was operated under actual clinical conditions. It was reported as giving satisfactory service.

In view of the favorable report based on the performance of this unit when employing cuff electrodes, the Council on Physical Therapy voted to include the Hogan Brevatherm Short Wave Diathermy Unit, Clinical Model 8820 (Two-Tube), in its list of accepted devices.

1. Mortimer, Bernard, and Osborne, S. L.: Tissue Heating by Short Wave Diathermy, *J. A. M. A.* 104:1413 (April 29) 1935.

HIGH TENSION DIATHERMY UNITS (MODELS 440 AND 480) ACCEPTABLE

Manufacturer: High Tension Corporation, New York.

These high tension diathermy units, designed for medical and surgical diathermy, are recommended for service in physicians' offices and in clinics.

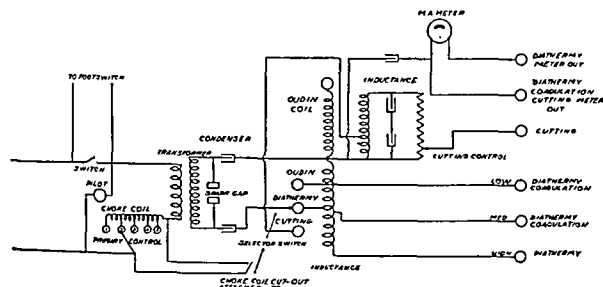

The electrical circuit was examined carefully and found to be efficient and reliable. The manufacturer submitted data containing a report of tests of the Model 480 for power input and output, and for its spark gap and transformer temperature rise. The results recorded in the data were in agreement with the observations conducted by an investigator for the Council and were in conformity with the standards for diathermy machines previously established. The input power required for these units is between 135 and 230 watts. Their frequency varies from 890 to 1,420 kilocycles per second, which corresponds to wavelengths between 211 and 37 meters.

The High Tension Diathermy Unit, Model 480, was tried out in a clinic acceptable to the Council. It was found to be satisfactory and met the requirements of the Council.

Model 440 is constructed essentially the same as Model 480 as far as electrical and mechanical characteristics are concerned, the difference being that Model 440 is designed for medical diathermy coagulation and desiccation, whereas Model 480 is also equipped with cutting current.

High Tension
Diathermy Unit,
Model 480.

Schematic diagram of circuit.

The Council therefore voted to include the High Tension Diathermy Units, Models 440 and 480, in its list of accepted apparatus.

CROSLY XERVAC—PRELIMINARY REPORT

Manufacturer: The Crosley Radio Corporation, Cincinnati.

According to the firm, the Crosley Xervac is an apparatus developed by Dr. Andrew A. Cueto for stimulating the growth of hair. The firm writes: "It [Xervac] is designed to stimulate and aid the growth of hair, and develop a healthy condition of hair and scalp by increasing the efficiency of the circulation of blood in the deep tissues of the scalp. This is accomplished by alternating positive and negative (vacuum) pressures which may be varied to suit the individual case."

The apparatus consists of a compressor and a vacuum pump, controls to regulate the pressures, and a helmet through which these pressures are applied to the scalp. It may be operated either by alternating or by direct current.

The theory, according to the firm, is that alternate vacuum and pressure of extremities of the body build up the deep network of blood vessels, thus supplying blood in sufficient quantities to desired points. This theory was claimed to be substantiated by a number of persons who have been treated in a clinic to indicate that development of the deep network of blood vessels in the scalp quite actively stimulates the growth of normal hair from hair follicles which heretofore had not been producing such hair.

Two of these units have been submitted to the Council on Physical Therapy for investigation along with an article which

was published in the *Journal-Lancet*, Minneapolis (56:571 [Nov.] 1936). In brief, the Council calls attention to the following points in connection with the Xervac:

1. Insufficient evidence has come to the attention of the Council to substantiate the alleged physiologic action.

2. The number of cases reported is insufficient on which to determine the usefulness of the device or to show what types of baldness, if any, respond favorably.

3. Insufficient evidence is presented to determine harmful effects, if any, connected with its use.

In view of the lack of critical evidence, physicians are advised for the present not to acquire the machine.

The Council therefore voted the Xervac inadmissible for inclusion in the list of accepted devices but will reconsider the apparatus without prejudice, if scientific evidence is submitted.

The Chemical Laboratory

THE FOLLOWING IS A REPORT OF THE CHEMICAL LABORATORY OF THE
AMERICAN MEDICAL ASSOCIATION.

P. N. LEECH, Director.

DENICOTEA

Two packages of Denicotea were submitted to the A. M. A. Chemical Laboratory for examination. One package contained one cigaret holder and ten cartridges. The cartridges were presumed to contain a silica gel to remove the nicotine and other ingredients in tobacco smoke. The label gave the following information:

"Smoke the healthy way.

Denicotea

assures you:

sound heart, sound lungs, sound
nerves, white teeth, unstained
fingers."

The second package contained ten cartridges. The label stated in French that the toxins of tobacco (nicotine, pyridine, ammonia and resinous acids) were removed from the smoke.

The cigaret holder was fashioned with a cavity in which a tube case could be inserted. The tube cases were colorless, brittle cylinders containing colorless, granular material. Qualitative tests showed the presence of silicic acid in the granular material.

After "smoking" four cigarets, the case and granular material had adsorbed a brown material with an odor of stale tobacco. This was partially soluble in water, ether, alcohol and chloroform. Qualitative tests indicated the presence of nicotine and traces of cyanides, pyridine and resinous material; ammonia was not found. Resinous material was found in the smoke after it had passed through the tube case.

For the determination of nicotine, average smoking conditions were reproduced as closely as possible. The smoke was "puffed" for ten seconds at intervals of ten seconds through the holder and passed through three wash waters. Eighteen puffs were taken and all but one inch of each cigaret was burned. The amount of nicotine in the water was determined by the method of Hofman (*Biochem. Ztschr.* 260:26, 1933). Two brands of cigarets were used.

Quantitative determinations yielded the following:

Nicotine per cigaret without filter (brand A).....	0.0017 Gm.
Nicotine per cigaret without filter (brand B).....	0.0020 Gm.
Nicotine passed by filter for average one of first four brand A cigaretts	0.00063 Gm. (40.1 per cent)
Nicotine passed by filter for average one of four brand A cigarets after six had been smoked.....	0.00082 Gm. (49 per cent)
Nicotine passed by filter for average one of first four brand B cigaretts	0.0011 Gm. (53 per cent)
Nicotine passed by filter for average one of four brand B cigaretts after four had been smoked.....	0.0014 Gm. (62 per cent)

From the foregoing figures it may be calculated that under ordinary conditions Denicotea removes approximately 60 cent of the nicotine from the smoke of brand A cigarets; new case is used and approximately 50 per cent after

cigarettes are smoked. It removes approximately 47 per cent from the smoke of brand B cigarettes when new and approximately 40 per cent after seven cigarettes have been smoked. It removes cyanides, pyridine and some of the resinous material from smoke. According to the experiments, the product is approximately 60 per cent efficient on the first smoke and its efficiency decreases, so that by the time twenty smokes are made through the same cartridge it would appear that there would be no appreciable denicotinizing effect at the end of the series.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
PAUL NICHOLAS LEECH, Secretary.

STANDARDIZATION OF DIGITALIS PRODUCTS ACCEPTED FOR N. N. R.

The Council has given extensive consideration to the question whether all the digitalis and digitalis-like preparations listed in New and Nonofficial Remedies should be standardized by the official U. S. P. method, even though they are also assayed biologically by any other acceptable method.

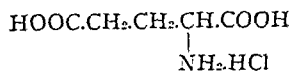

The various firms concerned were consulted and their replies were reported to the Council.

In the discussion based on these replies it was the consensus of the Council that, if two methods of assay do not give concordant results, more harm than good will be caused by creating the impression that a given preparation is standardized by both methods, for in the end its potency would be adjusted by one or the other and not by both. It is well known that many of the leading cardiologists and cardiac clinics employ the dosage recommended by Eggleston, which is based on the cat method of assay. No one, as far as it is known, has established an equally dependable therapeutic dosage based on frog units. In this connection it may be stated that digitalein and digitoxin are of approximately equal activity when assayed by the frog method, but digitoxin is ten times as active as digitalein when assayed by the cat method. Digitoxin is absorbed very well from the gastro-intestinal tract of man, digitalein is not.

The Council voted that manufacturers of digitalis and digitalis-like preparations be not required to change the method of standardizing such products as are now assayed by a satisfactory method.

GLUTAMIC ACID HYDROCHLORIDE-CALCO NOT ACCEPTABLE FOR N. N. R.

Glutamic Acid Hydrochloride-Calco was presented by the Calco Chemical Company for the Council's consideration as "a superior source of free hydrochloric acid for the treatment of Achlorhydria, Hypochlorhydria, Achylia Gastrica, Nervous Anorexia and Anemias (Requiring a High Protein Diet) and to Supplement or Replace Gastric HCl where such action is desirable." It is a solid substance which was presumed to yield hydrochloric acid when dissolved. A solid substance has an advantage in that it may be more easily transported by the patient. Glutamic acid hydrochloride has the formula:

The firm submitted a considerable amount of chemical data concerning the product but presented no references to the literature or other evidence of its clinical effectiveness as a conveyor of hydrochloric acid. The firm was informed that the Council was disposed to accept the product as a conveyor of hydrochloric acid, provided claims of superiority, as such, were not made; provided therapeutic claims for glutamic acid per se were not made; provided the product met the approval of the A. M. A. Chemical Laboratory, and provided no further conflicts arose.

The firm replied by sending advertising containing no claims for glutamic acid per se, nor any claims of superiority of the hydrochloride as a conveyor of hydrochloric acid, thus meeting two of the Council's objections.

The A. M. A. Chemical Laboratory found that the product complied with chemical tests and standards submitted by the firm. In view of the fact that the firm apparently based its opinion as to the usefulness of the product on laboratory assays, which did not include digestion experiments, the A. M. A. Chemical Laboratory was requested to undertake further examination, particularly with reference to the effectiveness of the compound as an acidifying agent in artificial digestion tests. The experiments were conducted in accordance with the U. S. P. X. Glutamic Acid alone was used in some experiments; in others, the solutions were adjusted to a hydrogen chloride content equal to 0.2 per cent hydrochloric acid, while in others the hydrogen ion concentration was rendered equivalent to that of 0.2 per cent hydrochloric acid (Glutamic Acid Hydrochloride contains three ionizable atoms—one due to the hydrogen chloride, and two to the glutamic acid). Controls were carried out with 0.3 per cent hydrochloric acid. Egg white was used as the substrate throughout. After many experiments the Laboratory came to the conclusion that glutamic acid hydrochloride inhibits peptic digestion in vitro.

The use of glutamic acid hydrochloride as a solid source of hydrogen chloride for peptic digestion is not new. More than ten years ago the Laboratory examined a brand of glutamic acid hydrochloride marketed by a well known pharmaceutical manufacturer under a trade name. The conclusions of the Laboratory were conveyed to that firm with the inquiry as to whether or not it had laboratory or clinical evidence for the value of its product. According to the firm's reply, its results confirm in general the observations of the A. M. A. Chemical Laboratory.

The Calco Chemical Company was informed that the Council felt itself unable to accept Glutamic Acid Hydrochloride for inclusion in New and Nonofficial Remedies unless more satisfactory evidence could be presented in favor of its usefulness. The Calco Chemical Company replied at length,¹ summarizing its contentions as follows:

1. The material has been shown to be definitely useful in stimulating gastric acid secretion and initiating normal gastric and duodenal function.

2. The material is a useful and convenient form of acid for substitution therapy.

3. The material does not inhibit gastric peptic secretion, although some diminution of peptic digestion does result, in vitro.

4. The material may be most effectively presented in an ethical manner by acceptance in New and Nonofficial Remedies.

The Council's referee, after careful study of the firm's reply, reported to the Council as follows:

"With respect to 1, the firm has not shown that glutamic acid hydrochloride stimulates gastric acid secretion or initiates normal gastric and duodenal function. The statement under 2 is only partly correct. Admittedly, glutamic acid hydrochloride would be a convenient form of substitution therapy provided it accomplished the purpose for which it is intended. That it is useful has not been demonstrated. With regard to 3, the firm has not shown that glutamic acid hydrochloride does not inhibit gastric peptic secretion, although the referee is willing to admit that the statement is probably correct. He agrees with the firm that peptic digestion in the presence of glutamic acid hydrochloride does not proceed as rapidly as in the presence of hydrochloric acid. Conclusion 4 requires no comment."

The firm stated that it intended to market the product whether accepted or unaccepted by Oct. 1, 1936. In view of the fact that the firm's reply furnished no conclusive evidence as to the usefulness of the product and that the investigations of the A. M. A. Chemical Laboratory cast considerable doubt on the therapeutic value claimed for it, the Council was obliged to declare it unacceptable for New and Nonofficial Remedies and to authorize publication of the foregoing report for the information of the medical profession.

1. Citing the work of Shay (Ann. Int. Med. 9:1628 [June] 1937) on the influence of glutamic acid hydrochloride on the titrable acidity of stomach contents.

REPORTS OF OFFICERS

NOTE.—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion.—Ed.

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association:

The following report of the Secretary is respectfully submitted:

MEMBERSHIP

The number of members enrolled on April 1, 1937, was 105,460. This enrolment is based on official reports received from the secretaries of constituent state and territorial medical associations and constitutes a new membership record. The number of enrolled members reported to the House of Delegates at the Kansas City session as of March 1, 1936, was 101,946.

It is quite probable that the number of members enrolled on the official membership list of the American Medical Association on April 1, 1937, is larger than the number of members actually enrolled on the same date on the official lists of the constituent state and territorial medical associations. In some states the names of members in arrears are dropped from the membership rolls on January 1, while in other states membership does not officially lapse on account of arrearages in payment of dues until some later date. Because of the interval between the time when names of members are actually removed from or added to the state association rolls and the time when notification of such changes reaches the office of the Secretary it is not possible to maintain exact uniformity in membership records. However, experience shows that in most instances the names of members temporarily suspended for nonpayment of dues are soon restored to official membership lists.

FELLOWSHIP

The number of Fellows of the Association, as shown by the official roster on April 1, 1937, was 66,296, as compared with 62,997 reported to the House of Delegates at the Kansas City session as of March 1, 1936.

As a part of this report, a table is presented which indicates the number of counties in each state and territory, the number of component societies as shown by the records in the Secretary's office, the number of members enrolled in the constituent associations at the time the count was made for the purposes of this table, and the number of Fellows, including Honorary Fellows and commissioned officers of government medical services.

REAPPORTIONMENT OF DELEGATES

Under the provisions of section 3, chapter I, of the By-Laws, it is required that a reapportionment of delegates shall be made every third year. The last reapportionment was made at the Cleveland session in 1934 for the years 1935, 1936 and 1937, and it will therefore be necessary to make a reapportionment at this annual session for the years 1938, 1939 and 1940.

AMERICAN MEDICAL ASSOCIATION BULLETIN

Publication of the AMERICAN MEDICAL ASSOCIATION BULLETIN has been discontinued by order of the Board of Trustees, and a special section known as the Organization Section of THE JOURNAL has been substituted. For a number of years the BULLETIN was issued as a monthly periodical during nine months of each year but did not serve as a satisfactory medium for the timely publication of important information pertaining to organization and medical economics. The circulation of the BULLETIN was limited almost entirely to Fellows of the Asso-

ciation, whereas THE JOURNAL reaches directly a much greater number of physicians than is included in the Fellowship of the Association and, as a weekly publication, provides facilities for more timely presentation of matters of general interest.

ANNUAL CONFERENCE OF SECRETARIES OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

The Annual Conference of Secretaries of Constituent State Medical Associations convened in Chicago in November 1936. All meetings were held in the new Assembly Hall in the Association's building. Nearly all the secretaries of the state

associations attended the conference, and with very few exceptions the editors of the official state medical journals were present. In addition there were in attendance a number of officers and members of official bodies of state associations and county societies, as well as the members of the Board of Trustees and of the administrative personnel of the American Medical Association.

This annual conference offers an opportunity for the executive officers of state medical associations and the editors of state medical journals to consider together problems of common interest, to secure information concerning methods and procedures that are used most effectively in organizational matters in the several states, and to familiarize themselves with the facilities of the American Medical Association that can be used for the benefit of the component and constituent units of the organized profession in the United States. The conference also provides opportunity for the members of official bodies and of the administrative personnel of the American Medical Association to secure first hand information concerning the problems with which state and county medical societies are immediately concerned and to obtain the benefit of suggestions and criticisms that may be useful in planning for the extension and helpfulness of the service of the national organization.

OFFICIAL CONTACTS

The number of visits made by members of the official and administrative personnel of the Association to meetings of medical societies in all parts of the country was considerably larger in 1936 than in any previous year. The elected officers, members of various councils and of other official bodies, and members of the administrative personnel of the Association have served as representatives of the Association at meetings or official conferences held in practically every state in the Union. The demand for field service of this nature is constantly increasing and at times has been almost overwhelming.

The number of invitations extended to official representatives of the Association to appear before important lay groups in various states is growing each year. As far as it has been possible, invitations received from medical societies and from influential lay organizations have been accepted, and a very earnest effort has been made to render the best service possible in the interest of better organization in the states and in furthering educational programs of component and constituent societies.

RESOLUTIONS TO BE SUBMITTED TO THE HOUSE OF DELEGATES

The following resolutions have been forwarded to the Secretary by Dr. Burt R. Shurly, delegate from the Section on Ophthalmology, for inclusion in the Secretary's report, in accordance with official action taken by the House of Delegates several years ago:

WHEREAS, The family physician has labored for these many years without full recognition of his valuable services; and

WHEREAS, The various school systems of the United States depend on the family doctor for the prevention and diagnosis of disease and the protection of the public; therefore be it

Resolved, That the school boards and authorities in charge of the school systems all over our country be respectfully requested to enter and file on the index card of every school child the name and address of the chosen family doctor; and be it further

Resolved, That the designated family doctor, together with the parents or guardians of the child or in their absence, be informed of any emergency that may befall the child in the schools of this country.

The office of the Secretary has continued to receive most helpful assistance from the secretaries and other officers of state, territorial and county medical societies, from the members of the various official bodies of the American Medical Association, including the House of Delegates, and from a large number of individual physicians in all parts of the country, for which sincere and grateful acknowledgment is hereby offered.

Respectfully submitted.

OLIN WEST, Secretary.

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

On June 20, 1936, Dr. James Tate Mason, who became President of the American Medical Association on May 12, 1936, died at his home in Seattle. That Dr. Mason had won a high place in the respect, esteem and affection of the members of the American Medical Association was clearly shown by the beautiful tribute that was paid to him by the House of Delegates when he was declared President of the American Medical Association, even though absent from the annual session at which he was to be formally installed into that office. Through Dr. Mason's death, the Association was deprived of the benefit of the willing and efficient service which he was prepared to render as its chief officer.

The Board of Trustees is glad to report to the House of Delegates that a properly designed scroll certifying to the action of the House of Delegates whereby Dr. Mason was proclaimed President of the American Medical Association was delivered to him in person before his death. A properly engraved gold medal, a copy of which is presented each year to the retiring President, could not be prepared in time for presentation to Dr. Mason himself but was forwarded to Mrs. Mason.

At the regular official meeting of the Board of Trustees held in Chicago on September 24, 1936, Dr. Charles Gordon Heyd of New York, elected Vice President of the Association by the House of Delegates at Kansas City, was declared President to serve in that capacity until the next annual session. The splendid and devoted service which Dr. Heyd has rendered in carrying out the duties of President of the American Medical Association has thoroughly justified this action, and the Board of Trustees desires to express its grateful appreciation of the wise counsel and the able assistance that Doctor Heyd has given to the Board in its consideration of matters demanding official attention.

Business Operations

For the twelfth consecutive year, the Board of Trustees is reporting to the House of Delegates an increase in the activities of the various councils, bureaus and departments of the Association. A marked increase in the number of members, a greater interest in organizational affairs on the part of physicians and a more widespread and more intelligent interest in medicine and in the public health on the part of the lay public are some of the factors that have produced a much greater demand for services of the kind which, in all probability, no other agency than the American Medical Association can provide. Changing social conditions and changes in the attitude of government toward medical and public health affairs, a constantly advancing knowledge of the scientific aspects of medicine and new problems growing out of important social changes affecting most of the relations of medicine have all contributed to the volume of inquiries, requests for information and appeals for aid of one or another kind that have at times greatly taxed the facilities of the Association.

The number of employees of the Association at the time of the preparation of this report was 565.

As will be seen from the Auditor's Report, which, with the Treasurer's Report, is submitted herewith, the gross earnings for the year ended Dec. 31, 1936, amounted to \$1,547,218.23, as compared with \$1,493,472.19 in the preceding year. Miscellaneous income, including income from investments, amounted to \$95,722.86. Operating expenses for the year were \$909,417.95, while Association expenses, including those incident to the operation of councils and bureaus, amounted to \$411,028.93, and miscellaneous expenses were \$209,382.37. The net income for the year was \$113,111.84, of which amount \$80,844.60 represented income from investments. Because of prevailing low interest rates, income from investments was less than in 1935.

Amounts expended for wages and salaries, for paper, for postage and for miscellaneous operating expenses were considerably larger than in previous years, and there were small increases in expenditures on other specific accounts. Decreased expenditures were recorded with respect to some items, but in practically all instances such decreases were small.

Expenditures for legal services and investigations were very considerably larger in 1936 than in 1935 because of suits brought

against the Association, all of which with one exception, have been withdrawn or have been dismissed by courts.

It is now apparent that operating costs will be considerably larger in 1937 than in 1936, because of higher costs of paper and other commodities.

The purchase of new machinery and equipment during the current year probably will require expenditures of from \$50,000 to \$70,000, of which approximately \$33,000 will be required for the purchase of a new gathering machine to replace out-worn equipment.

Summary

Gross earnings and miscellaneous income were larger in 1936 than in 1935. Expenditures for wages and salaries and for paper were notably larger than in the preceding year. Income from investments was smaller by approximately \$3,000 than in 1935. Net income for 1936 was \$113,111.84, of which sum \$80,844.60 was income received from investments.

Building and Equipment

During the year radical changes were made in the building of the Association located at 535 North Dearborn Street in Chicago. Two entirely new stories were added to the building, and an Assembly Hall and a large committee room were constructed above the eighth floor. Important alterations were made on all other floors. A full, detailed description of the building has appeared in the columns of THE JOURNAL. As a result of the enlargement and improvements, it has been possible to place the Editorial Department and the Library on one floor and to bring together other departments the activities of which are closely related. It has also been made possible to provide much needed room and better facilities for practically all departments, and there is now available space that can be used when further expansion may be necessary.

The new Assembly Hall is large enough to be used for meetings of the House of Delegates, for the Annual Conference of Secretaries of Constituent State Medical Associations and for the accommodation of other meetings as occasion demands. Congestion in the mechanical departments has been greatly relieved, and better working quarters and facilities have been provided. The brick walls on the Dearborn Street and Grand Avenue sides of the building have been replaced by entirely new walls of granite and Indiana limestone. The building now appears as a beautiful structure of which the Association can be justly proud. All building costs have been fully paid in accordance with the terms of contracts, and necessary adjustments in the building fund have been made, as shown in the financial reports that are appended herewith.

During the year it has been found necessary to make important additions to equipment in the printing department, including the purchase of two new linotype machines and additional presses. In the immediate future other new machinery must be secured, and the necessary appropriations for this purpose have been made by the Board of Trustees.

The Journal of the American Medical Association

During the year 1936 THE JOURNAL has maintained its repute as a leader in the general medical field.

Through cooperation with the United States Pharmacopeial Convention, THE JOURNAL has been publishing a series of articles on "The Pharmacopeia and the Physician," which have attracted wide attention and which have been of great service in encouraging prescribing of U. S. P. and N. N. R. products by the medical profession.

The special articles dealing with "The Therapy of the Cook County Hospital" have also been continued and will eventually be published in book form.

THE JOURNAL has cooperated with the United States Public Health Service in the publishing of a series of articles dealing with the diagnosis and treatment of venereal diseases.

Foreign correspondence has been extended by the development of correspondents in some countries not previously covered and by the inclusion of new material dealing particularly with the economic and social relations of medical practice in foreign countries.

THE JOURNAL has continued its earnest battle on behalf of high standards in the field of medical education and medical practice. Special issues have been devoted to graduate education, tuberculosis, general medical education, the work of the hospitals, roentgenology and clinical pathology.

The Editorial Department of THE JOURNAL has been still further developed by a shifting of emphasis somewhat from the purely laboratory and technical advances to material dealing especially with economics, general medical practice and the social aspects of medical work.

Attention is called to the further development of the department of questions and answers. This has now assumed such

proportions that from thirty to fifty letters are received each day from physicians throughout the world, who present not only problems arising in their practice but in many instances problems affecting their own health. It even has been suggested that this extensive department might warrant the publication either of a book devoted to questions and answers or of a special periodical including only such material.

In a survey of medical periodicals published in the *Bulletin of the Medical Library Association* it was indicated that THE JOURNAL leads all other publications in the world in the number of times that it is referred to in various medical writings.

Tables 1 and 2 indicate the approximate count of Fellows and subscribers carried on the mailing list of THE JOURNAL.

and the number of physicians receiving THE JOURNAL in each state.

The average number of copies of THE JOURNAL printed weekly during the year 1936 was 93,301, while the total number of copies printed during the year was 4,851,677. The net paid circulation on Dec. 31, 1936, was 93,270, an increase of 3,391 over the net paid circulation on a similar date in the previous year.

Summary

The Journal of the American Medical Association has continued to hold the place which it has long occupied as the leading publication of its kind.

New features have been developed during the past year. Special articles dealing with subjects of important interest to the entire profession, some of which have been prepared with the cooperation of other lead-

* This table gives the number of physicians (based on the Fourteenth Edition of the American Medical Directory) in the United States, the number receiving THE JOURNAL and the approximate percentage in each state. Copies to physicians in the United States Army and Navy are not included.

ing organizations, have been published. The amount of space devoted to foreign correspondence has been increased, and information concerning scientific, social and economic conditions in other countries has been presented.

In the editorial columns more attention has been given to economic and social aspects of medicine, but the quality of editorial material dealing with scientific matters has been maintained in accordance with high standards previously established.

The department devoted to questions and answers has assumed such proportions that from thirty to fifty letters are received each day from physicians in all parts of the world.

In a survey of medical periodicals published in the Bulletin of the Medical Library Association, it was shown that The Journal leads the medical publications of the world in the number of times it is referred to in medical literature.

Special Journals

The special periodicals issued by the American Medical Association have continued to serve as a source of stimulation and inspiration to the physicians interested in the specialties to which they are devoted.

During the year Dr. William Allen Pusey has retired as Editor of the ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY and has been elected by the Board of Trustees as Editor Emeritus of that publication. Under his leadership the ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY soon assumed and has since maintained a commanding position in the dermatologic periodical literature of the world. A special issue of the publication has been devoted to honoring him.

The ARCHIVES OF NEUROLOGY AND PSYCHIATRY dedicated the final issue for 1936 to Dr. Hugh T. Patrick, for many years Editor of that publication and instrumental in stimulating its establishment by the American Medical Association.

The AMERICAN JOURNAL OF DISEASES OF CHILDREN has rendered a special service by undertaking to publish monographic material which because of its cost and scope could not be published in any other manner.

Particularly important in the ARCHIVES OF INTERNAL MEDICINE are the monthly reviews and surveys of the status of various aspects of practice in internal medicine. Under the leadership of the editorial board of the ARCHIVES, these have developed such quality and importance that there are repeated demands for their republication in book form.

The other special periodicals have continued to maintain the high standards set in previous years.

All of the Association's periodicals in this group showed an increase in circulation for the year, the largest gains having been made by the ARCHIVES OF INTERNAL MEDICINE and the ARCHIVES OF OPHTHALMOLOGY. The total circulation of the special journals of the Association is not as large as is merited by the high quality of the material presented.

The loss incurred in the publication of the special journals for the year 1936 was \$33,821.30. Only two of the publications, the ARCHIVES OF OTOLARYNGOLOGY and the ARCHIVES OF OPHTHALMOLOGY, produced incomes in excess of the costs of publication.

As reported to the House of Delegates at the 1936 annual session of the Association, requests have been received by the Board of Trustees for the publication of additional periodicals in special fields. While it is believed that the special journals now published constitute a distinct contribution to scientific medical literature, and while these periodicals are not published with the view of financial gain, it is nevertheless true that the Association hardly can afford to extend its efforts in this direction unless proper support is given by the profession whereby continued deficits of comparatively large amounts can be prevented. Some of the special journals are now encountering competition, which did not previously exist, because periodicals devoted to special fields are being published by commercial concerns who do not maintain advertising standards comparable to those established and maintained by the periodicals of the American Medical Association.

As stated in the last annual report submitted by the Board of Trustees, some of the periodicals that have lately been established have been made the official organs of special organizations and apparently are receiving even greater support from physicians engaged in the practice of specialties than are the special publications of the American Medical Association. The Board of Trustees desires to continue the publication of this group of journals but feels very strongly that the special journals are worthy of whole hearted support by members of the specialties which they are designed to serve. Failing to receive such support, in the event that deficits continue to increase, it may become necessary to consider seriously the advisability of suspending publication of those special journals which are responsible for the largest part of the losses incurred.

Summary

The circulation of all the special journals was larger in 1936 than in the previous year, but the total circulation is not as large as is merited. Only two of the special journals produced incomes in excess of publication costs. The total loss sustained in 1936 was \$33,821.30. If deficits occasioned by the publication of this group of journals continue to increase, it may be necessary to consider suspension of publication of those responsible for the largest losses.

Hygeia

HYGEIA has maintained a steady increase in its circulation so that it has now reached the highest circulation in its history. Moreover, it is increasingly used as a source book for medical and health material by many other publications. Practically all of the popular periodicals which digest important material from other sources frequently present abstracts from HYGEIA. Magazines devoted to health in India, England, Germany, Russia, Canada and Australia have been quoting material taken directly from the pages of this publication. It is also used as a reference work in public schools in this and in some other countries.

In the publication of HYGEIA, the American Medical Association is rendering a service which could not, it may be said with assurance, be equaled by any other medical agency.

The net paid circulation for HYGEIA in December 1936 was in excess of 101,000, which represents an increase of approximately 15,000 over the circulation of the previous year. Approximately 16,000 physicians were subscribers in 1936. Woman's auxiliaries of various state medical associations secured a total of 5,541 subscriptions during the year. The aid thus given by the state auxiliaries is greatly appreciated by the Board of Trustees.

The advertising income from HYGEIA for the year 1936 was less than that of the previous year by approximately \$12,000. The total income received was less than the cost of publication by the sum of \$14,791.38, as compared with a loss of \$31,311.29 in 1935.

Summary

The paid circulation of Hygeia at the end of the year 1936 was more than 101,000, an increase of about 15,000 over the previous year. Much of the material that has appeared in this magazine has been reproduced in abstract form in popular periodicals, and many public schools have continued the use of Hygeia as a reference work. Publication costs exceeded income by the sum of \$14,791.38.

The Library

The demands for library service have increased steadily since 1920. The year 1936 has proved to be the year of greatest activity. During this year the Library has been provided with new and larger quarters and is far better equipped to meet the increased demands. The additional space has enabled rearrangement and correlation of various activities. The staff of the QUARTERLY CUMULATIVE INDEX MEDICUS now has adequate space for the immense amount of work involved in the preparation of this book. Ample stack room has been provided for a ten year collection of approximately 1,400 periodicals. The work of the entire Library staff has been greatly facilitated by assignment to the Library of such well planned and spacious quarters.

During the year, 10,852 periodicals were lent to physicians on individual requests. Thirty-five colleges and universities called on the Association for 937 periodicals which were not available in their various individual libraries.

The package library service, while not showing a great increase in the number of package libraries lent, nevertheless experienced one of its busiest years. There were 3,263 package libraries sent out in 1936. However, this figure does not include the folders on special subjects, which are being called for constantly for study in the Library and of which no record is kept. Approximately 100 visitors a month use the library facilities. The majority of package library requests were

received from the states in which are to be found the greatest number of medical libraries; namely, Illinois 385, New York 250, Ohio 196 and Pennsylvania 190.

The Library answered some 6,000 bibliographic and general reference questions. As usual, the indexes to THE JOURNAL were prepared in the Library.

The preparation of the QUARTERLY CUMULATIVE INDEX MEDICUS continued to constitute one of the major tasks of the Library. Twenty-three new periodicals were added to the number regularly indexed and approximately fifty additional periodicals were consulted, from the contents of which occasional articles were indexed. The loss for 1936 was \$3,643.57 less than for 1935.

During the year the Employees' Library showed a circulation of 5,400 books, with an average daily circulation of twenty-two.

Summary

New and enlarged quarters were provided for the Library in 1936, permitting rearrangement and correlation of the various activities and making it possible to meet more fully constantly increasing demands. Approximately 1,400 periodicals are now being received. During the year, 10,852 copies of periodicals were lent to physicians on individual requests. Library packages were distributed to the number of 3,263 in addition to a comparatively large number of folders on special subjects provided for the use of those who come to the Library for the purpose of study. Approximately 100 visitors a month use the Library facilities. About 6,000 inquiries of a bibliographic and general reference nature were answered.

The preparation of material for the Quarterly Cumulative Index Medicus constitutes one of the major tasks of the Library. Twenty-three new periodicals were added to the list of those regularly indexed, and occasional articles were indexed from approximately fifty additional periodicals. The costs of publication over income received from sales of the Index was less in 1936 than in the previous year by the sum of \$3,643.57.

The total circulation of books in the Employees' Library was 5,400, with an average daily circulation of twenty-two.

Cooperative Medical Advertising Bureau

The Cooperative Medical Advertising Bureau represents thirty-three of the official publications of constituent state medical associations. Commissions earned in 1936 amounted to \$30,598.63, as compared with \$26,224.26 in 1935. From the commissions earned, the sum of \$13,000 was remitted to the state medical journals represented by the Bureau, these remittances having been made in proportion to the total amount of advertising secured for each of the journals. Advertising contracts secured through the Cooperative Medical Advertising Bureau for the state medical journals concerned amounted to \$152,995.29, which represents a gratifying increase over the amount involved in contracts secured during the previous year.

The *Connecticut State Medical Journal*, the official organ of the Connecticut State Medical Society, was established in 1936 and is one of the participating journals of the Bureau.

Summary

Thirty-three of thirty-five journals of constituent state medical associations are represented in the Cooperative Medical Advertising Bureau. The total amount of advertising secured in 1936 was \$152,995.29. Commissions earned by the Bureau amounted to \$30,598.63, of which the sum of \$13,000 was remitted to the state medical journals represented by the Bureau in proportion to the total amount of advertising secured for each. The *Connecticut State Medical Journal* was added to the list of journals represented by the Bureau in 1936.

Mailing and Order Department

The total number of orders handled by the Order Department in 1936 was 69,819, with 343,977 units distributed. The Mailing Department handled 418,174 pieces of outgoing first

class mail, while 1,046,336 pieces of outgoing third class mail passed through this department.

A careful study has been made concerning the costs of shipping, and as a result shipping expenses have been somewhat reduced by resorting to the use of express facilities when the cost involved is less than that involved in shipping by mail.

Division of Foods, Drugs and Physical Therapy

In order that the work of the Council on Pharmacy and Chemistry, the Council on Physical Therapy and the Council on Foods might be better correlated and closer cooperation established in dealing with questions of common interest, completion of the plan for the creation of a Division of Foods, Drugs and Physical Therapy was carried out during the year.

This matter was brought to the attention of the House of Delegates at the Kansas City session. A committee on policy, rules and procedure, representing the three groups, has been established, and it is believed that the efficiency of the work of these councils will be greatly enhanced.

Council on Pharmacy and Chemistry

The work of the Council on Pharmacy and Chemistry was interfered with to some extent during a part of the year because of building operations, which, after completion, provided more ample space than was formerly available and thereby made possible the installation of much needed equipment and enlarged facilities.

SUBMISSION OF PRODUCTS AND COOPERATION OF MANUFACTURERS

There has been an almost constant increase in the number of products submitted to the Council for official consideration. It is gratifying to report that more and more important producers of pharmaceuticals are offering cooperation. Requests from manufacturers seeking opinion and advice concerning developments in drug therapy are being received much more frequently than before, and there is a very decided increase in the number of inquiries coming from physicians and official representatives of various organizations. It is encouraging to note that an appreciable number of manufacturers of drug products are revising catalogues to eliminate unessential and useless drugs and, in some instances, are discarding the use of therapeutically suggestive proprietary names which encourage self medication.

Another encouraging trend has been noted by the Council in that a number of pharmaceutical producers are now employing well qualified, scientific personnel in strengthening their laboratory and research facilities. The qualified opinion, advice and experience of the chemist, the bacteriologist and the physician are now being used to a far greater extent than ever before in connection with the production of therapeutic agents.

NOMENCLATURE

Some of the most difficult problems with which the Council has been confronted during its entire existence have been those concerned with nomenclature. During the past year the Council has been called on to give aid in devising nonproprietary names for new products, and the effort that has been made to be helpful in this connection evidently has been appreciated by the manufacturers.

Difficulties are rather frequently encountered in connection with the selection of names for newly discovered therapeutic agents. In some instances those who have developed entirely new compounds or products have coined names carrying distinct therapeutic implications, and this is not in accord with the basic rules of the Council. It is, of course, essential that the Council be consistent in its rulings with respect to nomenclature, and the acceptance of a therapeutically suggestive name would serve as a precedent that might easily create rather serious embarrassment later on. It is to be hoped that the time will come when investigators who have discovered new products will select names in compliance with the fundamentally sound rulings of the Council, opposed to therapeutically suggestive names. As an instance of the complications that sometimes arise in this connection, four different investigators, working independently within the last year, thought they had discovered

four new and different alkaloids of one drug. Later they all agreed that the four products were identical, but each had selected a name of his own. Because of this situation, the Council was compelled to coin a new and different name. Naturally, more than one of the investigators felt that the name he selected should have been accepted by the Council.

Rather chaotic conditions have existed with respect to the nomenclature of endocrine principles. In an effort to remedy this situation, the Council sought the aid of a group of consultants, each of whom has made important contributions to the knowledge of glandular physiology. This group constituted a committee known as the Advisory Committee on the Nomenclature of Endocrine Principles and included Drs. Edgar Allen, Willard M. Allen, J. B. Collip, G. W. Corner, E. A. Doisy, E. T. Engle, H. M. Evans, R. T. Frank, F. L. Hisaw, F. C. Koch, Leo Loeb, G. F. Marrian, C. R. Moore, Oscar Riddle, P. E. Smith and C. W. Turner. Three reports have been published by the Council on recommendations of this committee. These reports were carefully prepared after intensive study, and the Council has notified manufacturers of certain estrogenic products that it is now in position to consider evidence to determine acceptability or nonacceptability of these products. Other types of endocrine preparations will be considered when the Council is convinced that the time is ripe for their proper appraisal.

Other important questions that have received the attention of the Council deal with the nomenclature of vitamins when the pure principles have been isolated and with definitions of substances that may be produced through the use of entirely different methods.

REPORTS OF THE COUNCIL

For many years the Council on Pharmacy and Chemistry has published reports on submitted products through the columns of THE JOURNAL after such products have been accepted or rejected. Of late years a number of products giving promise of usefulness but in a purely experimental status when neither acceptance nor rejection is warranted have been considered by the Council. Such products have been made the subjects of preliminary reports. A number of such reports have been published during the past year, and some of them have attracted widespread attention. Among the products thus reported are chondroitin, cyclopropane, refined and concentrated antipneumococcic serum type VII, trichophytin and oidiomycin.

A cooperative committee representing the Council on Pharmacy and Chemistry and the Council on Foods, organized in 1935, continued its work during the past year and prepared an important report on the status of certain questions concerning vitamins. The demand for copies of this report was so great that it was necessary to have an extra printing. Those problems pertaining primarily to foods which received the consideration of the cooperative committee are reported on by the Council on Foods.

Another report of the Council dealt with decisions with reference to vitamin E and high potency viosterol preparations.

A special report of the Council had to do with the use of the terms "sterile," "sterilize" and "sterilization," the Council having been asked by the Food and Drug Administration of the U. S. Department of Agriculture to express an advisory opinion on the use of these terms. It is the contention of the Council that these terms should not be used other than in their correct, scientific significance, which indicates the absence or destruction of all micro-organisms.

During the year the Council has published numerous reports on products that were not found acceptable for inclusion in New and Nonofficial Remedies. In some instances producers have taken off the market some of the products dealt with in these reports, while in other instances the Council has been asked to withhold final action until satisfactory convincing evidence justifying claims made can be offered.

PUBLICATIONS OF THE COUNCIL

New and Nonofficial Remedies.—In previous years New and Nonofficial Remedies has been revised annually, and supplements have been issued at various times during each year in order that subscribers may be properly informed concerning products that have been found acceptable in the interim between annual editions of this publication. In 1936 the issuance of a

new edition of New and Nonofficial Remedies was delayed for the reason that the U. S. Pharmacopeia and the National Formulary did not become official until June 1, 1936. The revision of the Pharmacopeia and of the National Formulary made it necessary to reedit and reset completely all material included in New and Nonofficial Remedies. The arrangement of the 1937 volume will differ from that of previous editions and will include a number of new products accepted for inclusion during the year 1936. A considerable number of products that formerly were included in New and Nonofficial Remedies will be omitted from the 1937 volume.

Epitome of the U. S. Pharmacopeia and National Formulary.—The issuance of the new decennial editions of the U. S. Pharmacopeia and the National Formulary made necessary a drastic revision of this publication of the Council. The original printing of 5,000 copies was quickly exhausted, and a second printing was necessary.

Useful Drugs.—The book Useful Drugs continues to enjoy wide popularity. The selected list of drugs contained in this book is used by many individual physicians and as a text in a number of medical schools. It was revised during the year in order to bring it into conformity with the new Pharmacopeia and National Formulary. During 1936 more than 7,400 copies of this book were distributed.

Glandular Physiology and Therapy.—In December 1935 a series of articles on glandular physiology and therapy that had appeared in THE JOURNAL was printed in book form. During 1936, 5,300 copies of this book were distributed and a second revised printing was made. This book will shortly be published in German, and arrangements have been made for a Polish translation. Because of the illness of one of the official translators a proposed French translation had to be given up, and a Spanish translation was interfered with because of the development of the civil war in Spain. Arrangements for translation into Italian are still pending.

Hospital Practice for Interns.—Revision of this publication was begun late in 1936, but the new and revised volume will soon be ready for publication under the joint auspices of the Council on Medical Education and Hospitals and the Council on Pharmacy and Chemistry. This book is intended as a reference book for the intern and for the practicing physician. In no sense is it intended to serve as a textbook.

SPECIAL INVESTIGATIONS

Catgut Sutures.—With the aid of a special committee appointed by the Council on authorization of the Board of Trustees, an investigation of catgut sutures on the market was undertaken. Examinations were made of approximately 1,100 sutures, purchased for the most part on the open market. The official report on this investigation had not been published at the time of the preparation of the report of the Council, but the manufacturers of catgut sutures have been informed of the conclusions of the committee, and beneficial results already have become apparent.

Nonspecific Protein Therapy.—The Council has under way an investigation of certain problems pertaining to nonspecific protein therapy.

Injection Treatment of Hernia.—A questionnaire pertaining to the injection treatment of hernia has been sent to physicians and hospitals in various parts of the country. After a careful analysis of replies received, the Council issued a report on the status of this particular method of treatment.

MEMBERSHIP OF THE COUNCIL

Dr. Reid Hunt, a member of the Council since its creation in 1905, submitted his resignation March 1, 1936, at the time of his retirement from the faculty of Harvard University. Dr. Hunt's resignation was accepted with genuine regret. As a member of the Council on Pharmacy and Chemistry for more than thirty years and as its chairman from 1927 to 1936, Dr. Hunt rendered invaluable service.

During the year Dr. E. M. K. Geiling, professor of pharmacology at the University of Chicago, was elected to succeed Dr. Hunt, and Dr. W. C. Rose, professor of biochemistry at

the University of Illinois, was elected to fill the place formerly occupied by Dr. Lafayette B. Mendel, whose death was previously reported.

Summary

There is a rather constant increase in the number of products submitted for official consideration by the Council on Pharmacy and Chemistry and a gratifying tendency toward better cooperation on the part of producers of pharmaceuticals. A number of producers are strengthening their laboratory and research facilities and are utilizing the services of well qualified scientific investigators.

The general subject of nomenclature of therapeutic agents has demanded much attention on the part of the Council. Chaotic conditions have existed with respect to the nomenclature of endocrine principles and, through the aid of a group of consultants, it is believed that important contributions have been made to the knowledge of glandular therapy.

The established publications of the Council have been continued, with necessary revisions, and several special reports have been prepared and published.

The Council, with the aid of a special committee, has conducted an investigation of catgut sutures on the market. It also has instituted a special investigation of certain problems pertaining to nonspecific protein therapy.

Council on Physical Therapy

CONSIDERATION OF APPARATUS

Probably one of the most important functions of the Council is the publication of reports on apparatus submitted and investigated, as well as on apparatus offered for sale that is not submitted for consideration. The consideration of short wave diathermy machines took the lead for the year over all other apparatus. In view of the investigative work in the therapeutic usefulness of these machines, the Council feels justified in stating that, based on present available evidence, (1) there is no specific biologic action of high frequency currents, (2) there is no specific bactericidal action, and (3) the therapeutic effect is due to the heat produced. Twelve short wave diathermy machines were accepted. Many more were considered, some of which were rejected, while others are still under consideration.

It has come to the attention of the Council that many of these units will interfere with radio communication. The Council has gone on record to the effect that short wave machines will not be accepted in the future unless they are protected by filters or other devices to minimize interference. Among the appliances considered and accepted were positive and negative pressure machines, diathermy machines, vaporizers, inhalators, hearing aids, ultraviolet and infra-red devices, and oxygen therapy equipment.

EDUCATIONAL ACTIVITIES

Another important function of the Council is its educational activities. These are sponsored in a large measure by the consultants on education appointed by the Council on Physical Therapy. A number of state and county medical societies have cooperated by having discussions of physical therapy on their programs. Reports have come to the Council that young physicians are now taking graduate courses in physical therapy at various institutions.

Films available for loan by the Council have been shown at about thirty-five institutions and medical gatherings. At least eighteen lectures on physical therapy were given in various localities by the members of the Council. Twelve exhibits, including the exhibit at the regular annual session of the Association at Kansas City, were staged in cooperation with the Committee on Scientific Exhibit of the American Medical Association. The Council still believes that there is a vast opportunity for spreading information concerning the value of physical therapy among general practitioners. The Council is particularly anxious to make known the value of heat, massage and exercise. In the opinion of the Council, a very narrow view of the possibilities of physical therapy is pre-

sented to physicians by the representatives of manufacturers of apparatus calling on them. The consultants on education and the Council itself will attempt to secure speakers for medical societies.

In the course of the year, eight special articles were published in *THE JOURNAL*. These articles have been widely read and many reprints have been furnished to physicians on request. Among those which brought forth comment was the "Report of the Committee on the Present Status of Physical Therapy." In this, its second report, the committee pointed out that the status of physical therapy in its relation to general medicine has improved considerably since the first report ten years ago, in that there is a better understanding of the field as a whole by the physicians generally, that the usefulness and limitations of physical therapy agents are better understood and that the activities of the Council in its attempt to disseminate reliable information on this subject have been well rewarded.

Oxygen therapy, artificial fever therapy, passive vascular exercise and other important physical therapeutic measures that have been established within the last decade have received consideration.

The article "The Interrupted Low Frequency and the Constant Electric Current in Medicine" was the first adopted pronouncement of the Council on this subject. The scope and limitations of the field were discussed and a statement of possibilities of the agents was given.

SPECIAL INVESTIGATIONS

Shoes.—Progress is being made in the consideration of orthopedic equipment, including shoes. Consultants skilled in orthopedic surgery, appointed by the Council, have been preparing regulations for the consideration of shoes. While the specifications are not yet complete, the Council hopes to publish its report in the near future.

Audiometers.—A group of otologists has been appointed and is preparing regulations for acceptable audiometers and hearing aids. The American Society for the Hard of Hearing and the American Standards Association have cooperated in the consideration of hearing aids and audiometers.

Ophthalmologic Devices.—In cooperation with the Committee on Standardization of Instruments and Drugs of the Section on Ophthalmology of the American Medical Association, certain ophthalmic appliances for which therapeutic and diagnostic claims are made have been investigated and reported on in *THE JOURNAL*.

Research.—During the past year the Council awarded six grants to aid in research. These grants are made available to physicians and investigators who make application and who, in the opinion of the Committee on Research of the Council, have a problem of merit.

Handbook of Physical Therapy.—The second edition of the Handbook of Physical Therapy was completed this year. New chapters have been added and the entire book has been revised. In the opinion of the Council, the Handbook is more practical than the original edition and should be of great value to the general practitioner. Apparently it has been well received by the profession, since the original printing of 4,000 copies has been exhausted.

Apparatus Accepted.—The booklet "Apparatus Accepted" has again been revised to include all the products that have been accepted up to December 1936. When this booklet is revised, it is expected to be made larger by the addition of general discussions and will conform in general appearance to New and Nonofficial Remedies.

Seal of Acceptance.—A seal denoting acceptance of a product has been adopted by the Council on Physical Therapy.

The Council is greatly indebted to a number of physicians in various parts of the country, who have rendered most able assistance in promoting its work.

CHANGES IN MEMBERSHIP

In the death of Dr. F. J. Gaenslen the Council lost one of its most honored and efficient members.

Dr. George Miller MacKee and Dr. Robert B. Osgood, after several years of splendid service, found it necessary to resign because of other important duties.

Dr. Frank Dickson, Dr. Frank R. Ober and Dr. George C. Andrews were elected to succeed Drs. Gaenslen, MacKee and Osgood.

Summary

Consideration of apparatus is an important function of the Council. Appliances and devices considered have included wave diathermy machines, positive and negative pressure devices, vaporizers, inhalators, hearing aids, ultraviolet and infra-red lamps, and oxygen therapy equipment and apparatus intended for use in ophthalmology.

A number of state and county medical societies have cooperated with the Council by making programs on physical therapy available to their members. The Council feels that there is need and opportunity for disseminating information concerning the value of physical therapeutic measures among the general practitioners. The Council and its consultants will gladly cooperate with medical societies in securing speakers. Films are available for loan to medical societies that are interested.

Regulations for acceptable audiometers, orthopedic equipment including shoes, and radon preparations are now being prepared.

Six grants to aid in research on physical therapy problems were awarded.

New chapters have been added to the Handbook of Physical Therapy, and the entire book has been revised and published.

"Apparatus Accepted" has been revised to include all of the products that have been accepted up to December 1936.

The Council on Physical Therapy has adopted a seal of acceptance.

Council on Foods

The Council on Foods was first organized as a subcommittee of the Council on Pharmacy and Chemistry in an era characterized by the promulgation of extravagant nutritional claims for many ordinary foods. Misleading health claims were presented to the public over the radio, on cards in grocery stores and drug stores and even in restaurants, on bill boards, in newspapers and in magazines of both popular and semiscientific character. Today, partly as a result of the activities of this group, now known as the Council on Foods, these extravagant or misleading claims are seen and heard much less frequently.

Manufacturers of useful products who formerly resorted to more or less bizarre advertising have notified the Council that they have discontinued the use of such advertising and desire to have their products accepted by the Council and to comply with the Council's rules.

GENERAL POLICIES

The objectives of the Council on Foods are much clearer now than when the Committee was founded primarily to pass on health claims made in the advertising of food products. The Council not only passes on advertising claims but seeks to maintain high standards for food products, these standards being set by appropriate governmental agencies. The Council has reached an eminence where it is consulted frequently by public health officials and other officers charged with the maintenance of community standards for food products.

While maintaining its work in summarizing statements of policy toward claims made for foods, the Council has more recently undertaken to prepare reports on the nutritional significance of different classes of foods. These are published from time to time as general decisions and reports of the Council. It is anticipated that more and more of the Council's facilities will be directed in the future toward the preparation of educational reports on foods. These will fill a need which is met by no other organization. The reports that have been issued to date have met with a favorable response on the part of individual physicians and nutritionists.

LIMITATION OF SCOPE OF FOODS CONSIDERED

Early in 1936 the Council decided that it might well conserve its facilities by eliminating its attention from those classes of foods which least require attention. It was decided that ordinary bread and ordinary bakery products need no longer be considered. Manufacturers of accepted products were thereupon notified in advance that acceptance would be withdrawn on Jan. 1, 1937. All possible consideration was given so that manufacturers who had cooperated with the Council might use up current advertising and labels which bore the seal. With its action on bread, the Council began to plan to limit its scope even further and has eliminated a number of food products from consideration.

In limiting its scope, however, the Council has made it clear that it will review nutritional claims made in the advertising of food products of any class when such action is considered to be in the interest of the public and the profession.

NEW PRODUCTS ACCEPTED

The Council has, by its policy of limitations, relieved the office of considerable correspondence and has been able to begin again the acceptance of food products that fall within its scope. During the year 1936 a number of manufacturers who heretofore did not have their products accepted agreed to abide by the rules and decisions of the Council in their advertising and thus have had their products declared accepted, and the influence of the Council has been spread to that degree.

VITAMIN D FORTIFIED MILK

One of the problems to which the Council has devoted considerable attention is the fortification of foods with vitamin D. The Council and, of course, the medical profession in general have viewed with concern the tendency on the part of some manufacturers to add vitamin D to ordinary foods. The Council believes this practice encourages undue advertising emphasis but rarely serves any demonstrated need of public health or welfare. A policy toward fortification of foods with vitamins has been adopted by the Council and formulated as a general decision. A food is considered "fortified" if it is enhanced as to vitamin content or potency by the addition of vitamin concentrates, or of natural products of extraordinary vitamin potency, or by other means accomplishing the same results. In order that a fortified food may be accepted, the firm must present evidence that there is a definite need for an increased intake of the particular vitamin in question and that the food to which the vitamin is added is particularly suited as a vehicle. The Council has previously declared that a number of foods did not warrant fortification with vitamin D; namely, beer, cake, cake flour, ice cream, cheese and sausage and such accessories as chewing gum. More recently the Council has voted that, in view of the evidence now available, it will accept no vitamin D fortified food other than milk. Vitamin D is concerned with the metabolism of calcium and phosphorus. Milk provides an excellent source of these two dietary essentials. Furthermore, it has been observed by pediatricians that infants may consume vitamin D more regularly when it is incorporated with the milk.

In the vitamin D milk report, which was published in the issue of THE JOURNAL dated Jan. 16, 1937, but which was transmitted to the industry in the latter part of 1936, the Council has set up standards by which vitamin D milk will be considered and declared acceptable. No milk containing less than 135 or claiming more than 400 U. S. P. units of vitamin D per quart will be accepted. Milk containing less than 400 units per quart has enhanced nutritive value and when consumed in customary quantities (from 1½ ounces for each pound of body weight in early infancy and 1½ pints or more daily in later infancy) will prevent clinical rickets in infants. For milk containing 400 U. S. P. units per quart, it may be claimed that a margin of safety in the intake of vitamin D is provided, if the milk is ingested in the usual amounts prescribed by physicians. There must be no intimation in advertising of accepted vitamin D milks that the Council favors the use of any vitamin D fortified milk over the prescribing of other forms of vitamin D for infants or recommends the use of vitamin D milk to the exclusion of an additional supply of the vitamin in some other form. To be acceptable to the Council, bottle caps

and labels must declare the potency and the source of the vitamin D. Otherwise the standards of maintenance of quality previously in operation are enforced.

GENERAL DECISIONS OF THE COUNCIL

Among other problems considered by the Council on which general decisions have been published are an amendment of the rules governing use of the seal, an amendment of the decision on vitamin E claims in advertising directed to the public, a decision on the classification of yeast products, a discussion intended as a guide to advertisers on the subject of energy claims for foods, and a brief discussion of the desirable nutritional features of diets used for the reduction of weight and the requirements of foods for weight reduction.

REPORTS OF THE COUNCIL

There is considerable interest in the nutritional properties of different classes of foods. At the present time there exist no comprehensive and unbiased reviews of the nutritional properties of commercially prepared foods. It was believed that brief accounts of the available evidence on the nutritional significance of different kinds of foods would be valuable not only to physicians but to nutritionists, public health officers and manufacturers. The first report in this series was on vitamin D milk and consisted of a comprehensive critical review of the literature by Dr. Philip C. Jeans. This was submitted as a report to the Council, discussed principally the available evidence on the relative value of different varieties of vitamin D milk for infants, and served to summarize and to evaluate the many apparently conflicting reports in the literature.

Another report that has attracted some attention is one on the nutritional significance of bran. The Council concluded that bran is a useful food for many persons, particularly as a source of bulk in the diet, but according to available evidence there are some individuals who cannot tolerate bran. The Council therefore reaffirms its previous stand that statements relative to the relief of constipation must be reproduced in full as follows: "Constipation due to insufficient roughage in the diet should yield to bran when eaten regularly. A competent physician should be consulted in cases not corrected in this simple manner."

In recent years much attention has been directed to the vast amount of experimental evidence that has accumulated on the composition and nutritional value of gelatin, a food that has been recommended for inclusion in the diet of infants and for the feeding of patients with certain myopathies. The Council has reviewed the evidence and has reached the conclusion that gelatin, properly made, is a wholesome food and has special usefulness when one desires to add variety to the diet. The claim that gelatin is an *aik* in the digestion of milk is, in the opinion of the Council, not established at present. The claim that gelatin is of particular value as a source of aminoacetic acid for the treatment of some of the myopathies cannot be recognized. Even though gelatin contains 25 per cent of aminoacetic acid, the dosage of this acid in the treatment of myasthenia gravis or pseudohypertrophic muscular dystrophy is usually from 20 to 30 Gm. and it is apparent that gelatin can furnish only a small proportion of the proper dosage. Other reasons for not recognizing this claim are discussed in full in the published report.

The past year has witnessed a reorganization of the administrative offices of the Council. Along with the Council on Physical Therapy, the headquarters office of the Council on Foods is housed with the Council on Pharmacy and Chemistry. This placing together of the staffs of the three councils makes for closer cooperation in the activities of these three groups and insures the maintenance of similar policies toward problems of a similar nature that confront each council. The present staff of the Council on Foods now includes Dr. Ruth Cowan Clouse, who has returned after a leave of absence due to illness, Miss Marjorie Pickens, who has completed the work for degree of Doctor of Philosophy in physiologic chemistry at Yale University, a secretary and five office assistants.

MEMBERSHIP

The Council on Foods records with sorrow the death of one of its members, Dr. Edwin O. Jordan, Sept. 2, 1936. Dr. Jordan

was elected a member of the Council in 1933. He gave his time and counsel unselfishly, and his loss is felt keenly by the members. The Council also lost by death, Nov. 11, 1936, one of its former members, Dr. William McKim Marriott, who served on the Council from 1929 to 1931.

Dr. Howard B. Lewis, professor of biologic chemistry, University of Michigan, was elected to the Council in 1936 and Dr. James S. McLester, at the request of the Council and the Board of Trustees, resumed a membership interrupted by his election as President-Elect of the American Medical Association.

CONSULTANTS

The following persons were called on as consultants during the year, and the Council and the Board of Trustees gratefully acknowledge appreciation of their services: Dr. Walter C. Alvarez, Dr. R. M. Bethke, Miss Ruth Blair, Dr. Margaret Hessler Brookes, Dr. Daniel C. Darrow, Dr. George B. Eusterman, Dr. H. J. Fisher, Miss Mary A. Foley, Dr. Grace MacLeod, Dr. Isabel Noble, Dr. Henry C. Sherman, Dr. Genevieve Stearns and Dr. Dwight L. Wilbur.

Summary

The objectives of the Council on Foods are now much more clearly defined than previously in that efforts are being directed toward the maintenance of high standards for food products as well as for improvement in the nature of advertising.

Reports dealing with the nutritional significance of different classes of foods are now published as general decisions and reports of the Council, and it is expected that in the future these educational reports will constitute a distinct feature of the Council's work. Many food products formerly included in the scope of the Council's consideration are no longer so included, but the Council will continue to review nutritional claims made in the advertising of food products.

Special consideration has been given during the past year to the subject of fortification of foods with vitamin D, and a food is now considered "fortified" if it is enhanced as to vitamin content or potency by the addition of vitamin concentrates or of natural products of unusual vitamin potency or by other means accomplishing the same results. It is required that convincing evidence of a definite need for an increased intake of the particular vitamin in question shall be presented and that the food to which a vitamin is added is suited as a vehicle before a fortified food can be accepted for inclusion in the Council's official lists. In view of the nature of available evidence, the Council has decided that no vitamin D fortified food other than milk will be accepted. Standards by which vitamin D milk will be considered and declared acceptable have been established. No milk containing less than 135 or claiming more than 400 U. S. P. units of vitamin D per quart will be accepted.

Important decisions have been made by the Council with respect to advertising claims on vitamin E, the classification of yeast products, nutritional features of diets used for the reduction of weight and the requirements of foods intended to be helpful in effecting weight reduction, as well as decisions pertaining to bran, gelatin, and other products that have been widely used but the status of which heretofore has not been definitely fixed.

The Council has had the benefit of the advice and counsel of a number of distinguished physicians and scientists who have served as consultants, and their helpful service is gratefully acknowledged.

Chemical Laboratory

The Chemical Laboratory has been remodeled and enlarged in order that it may better meet constantly increasing demands. Important additions include an accurately air conditioned micro-analytical room and a room in which physical equipment, including a photospectroscope, has been installed. These new facilities will enable the Laboratory to take full advantage of advanced methods in chemistry and thereby to save much time that was formerly taken up because of the enforced use of

older and slower methods. The Association's Chemical Laboratory is now a well balanced unit equipped for both micro-chemical and macrochemical analysis as well as for physical chemical measurements.

In addition to the Director, four other splendidly qualified chemists are members of the Laboratory staff. The new Laboratory and the work that is being done have attracted great interest among chemists, and many professional men have called to inspect the arrangement and equipment.

During the past year in spite of the fact that it was necessary to close the Laboratory for several months because of building operations, a number of important problems have received attention and many products widely used in the practice of medicine have been carefully studied, including crystalline insulin, crystalline vitamin D, allantoin, pantocain, silver picrate, strophanthin and a number of hypnotic drugs. In addition, the Laboratory has, so far as possible, performed the usual services for the Bureau of Investigation and for other departments of the Association.

With the new equipment now available and with increased personnel, it is possible for the Laboratory to make important analyses in much less time and, in some instances, with greater accuracy than heretofore. By the use of the methods of micro-analysis and spectroscopy, it is now possible to make determinations with far smaller amounts of products to be examined than could be done under older analytical methods. In one instance a drug costing approximately \$2,000 a gram was submitted for analysis. Through the use of microchemistry and photospectroscopy, it was possible to make the necessary determinations with a minute amount of this product, and significant savings were thereby effected. In another instance a preparation offered for sale at \$20 per ampule was found to contain approximately one part of indigo in 100,000 parts of water.

The largest part of the work of the Laboratory is concerned with products submitted for the consideration of the Council on Pharmacy and Chemistry and with making investigations designed to insure the purity and the potency of accepted products.

Summary

The Chemical Laboratory has been remodeled and enlarged, and important modern equipment has been installed. The Laboratory is most largely concerned with matters referred by the Council on Pharmacy and Chemistry and the Bureau of Investigation but also undertakes independent investigations.

Bureau of Legal Medicine and Legislation

FEDERAL LEGISLATION

The Seventy-Fourth Congress expired with the adjournment of its second session, June 20, 1936. The bills of interest to the medical profession that were pending when the Board of Trustees prepared its report for submission to the House of Delegates in 1936 were briefly discussed in that report. Before the Congress adjourned, it enacted legislation to carry into effect three of the legislative proposals there discussed. Provision was made for the restoration and maintenance of medical units in the Reserve Officers' Training Corps. The tax payable under the Harrison Narcotic Act by universities, colleges, schools and laboratories using narcotic drugs for purposes of research, instruction and analysis was reduced from \$24 to \$1 a year. Provision was made whereby any clinic operated for charity and not for profit might obtain alcohol free from federal tax for use within the activities of the clinic, including use for the compounding of bona fide medicines for the treatment of clinic patients outside the clinic. All other federal legislation discussed in the report of the Board of Trustees in 1936 lapsed with the expiration of the Seventy-Fourth Congress.

With the convening of the Seventy-Fifth Congress, in January 1937, there came the usual flood of bills, some new and some bills that had been introduced in the previous congress or possibly in many previous congresses without having been favorably acted on. The Bureau of Legal Medicine and Legislation has endeavored to keep in touch with all these bills so far as they are of direct interest to the medical profession and the public health of the country and has endeavored to keep the profession informed concerning them through the columns of THE

JOURNAL. Some of the more important bills possibly call for brief discussion here.

United States Department of Health.—The President of the United States transmitted to Congress, Jan. 12, 1937, a message in which he stated that it would be necessary to establish a Department of Social Welfare. Accompanying that message was a report from the President's Committee on Administrative Management in the Government of the United States, in which the committee outlined the functions of the proposed department as follows:

"To advise the President with regard to social welfare.

"To administer Federal health, educational, and social activities; to conduct research in these fields; to administer Federal grants, if any, for such purposes; to protect the consumer; to conduct the Federal aspects of Federal-State programs of social security where need is the basis of payment to beneficiaries; to administer all Federal eleemosynary, corrective, and penal institutions; and to administer probation and parole." Senate Document No. 8, 75th Congress, 1st Session, page 61.

The President's message and the report of his committee were, at the date of the writing of this report, under consideration by a joint committee of the Senate and the House of Representatives. Action to preserve the integrity of medicine and the public health administration and looking toward the establishment of a Department of Health independent of the proposed Department of Social Welfare was taken by the Board of Trustees and is discussed elsewhere in this report.

Federal Health Insurance.—The Social Security Board has been and is engaged in the study of social insurance. It is understood that this study covers health insurance only as an incident in the larger program. It seems probable, however, that the board will ultimately make an intensive study of health insurance as such. A bill (S. 855, 75th Congress) for the establishment of a system of federal health insurance was introduced by Senator Capper of Kansas, January 15, and is now pending in the Senate Committee on Finance. The bill, prepared by or under the direction of Abraham Epstein, follows closely the other bills which have emanated from that source.

Taxation Under Social Security Act.—The social security act became a law Aug. 14, 1935. Physicians and medical associations have been directly affected by it only as employers and employees. In those relations they have the same status as other employers and employees. Their medical status does not of itself entitle them to any special benefit or subject them to any special burden. A medical association, however, may be exempt from taxation as an employer if organized and operated exclusively for scientific or educational purposes, provided no part of its net earnings inures to the benefit of any private shareholder or individual. This does not prevent such an association from carrying on such administrative activities as are necessary to accomplish its scientific and educational purposes, but just how far such administrative activities may go is a matter that must be determined in each instance by the Commissioner of Internal Revenue, on the basis of evidence submitted. Exemption should be formally established through the office of the Commissioner of Internal Revenue, on proper application by the interested association.

Medical Services for Federal Employees.—Under the United States Employees' Compensation Act, an employee of the federal government who suffers injury or develops disease attributable to his duties is entitled to medical and hospital services at government expense. Such services must be furnished by or on the order of United States medical officers and in United States hospitals, if this is practicable. If it is not practicable, medical and hospital services may be furnished by or on the order of private physicians and hospitals designated or approved by the United States Employees' Compensation Commission. In the designation and approval of private physicians the commission limits its choice to doctors of medicine duly licensed to practice medicine. In its designation and approval of hospitals it recognizes only reputable hospitals. A bill has been introduced in the Seventy-Fifth Congress (S. 1233 and H. R. 4650) proposing to give to every licensed osteopath, so far as designation and approval by the commission is concerned, the same status as that of doctors of medicine. This bill is before the committees on the judiciary of the houses in which they respectively were introduced.

Sale of Helium by the Bureau of Mines.—The House of Delegates, at its 1936 session, adopted a resolution approving the allotment by the federal government of helium for therapeutic use (Proceedings, House of Delegates, 1936, pp. 55 and 65). A bill has been introduced in the Senate (S. 1567, 75th Congress) and in the House of Representatives (H. R. 4415, 75th Congress) authorizing the sale to citizens of the United States or to United States corporations, under regulations approved by the President, of any helium produced by the United States Bureau of Mines that is not needed for government use. This bill has the support of the Secretary of the Interior. It is pending in the committees on military affairs of the Senate and the House.

Contract Surgeons of the Spanish-American War.—Bills have been introduced to restore the pensionable status of veterans and female nurses who served during the Spanish-American War, to provide similar benefits for male nurses, and to do likewise for teamsters and others. The contract and acting assistant surgeons who rendered such valuable service have been neglected. The status of contract and acting assistant surgeons was considered, however, by the Committee on Pensions of the House of Representatives when H. R. 4013 (later reintroduced and reported favorably as H. R. 5030) relating to the pensions of veterans and female nurses was under consideration. As contract surgeons and acting assistant surgeons were not technically a part of the military forces, they were not included; their inclusion in the bill would render enactment of the bill more difficult and might even lead to its veto and thus lessen the chances of the veterans and female nurses obtaining the legislation that they seek. So far as can be learned, it is for this reason that contract surgeons and acting surgeons are to be denied, for the present at least, the benefits given others who rendered service no more meritorious than theirs.

Foods, Drugs, Therapeutic Devices and Cosmetics.—Before the Seventy-Fourth Congress adjourned, the Senate had passed a bill (S. 5, 74th Congress) for the better regulation of interstate commerce in foods, drugs, therapeutic devices and cosmetics. The House of Representatives struck out all after the enacting clause of the Senate bill and inserted an entirely new bill, which it then passed. The bill passed by the Senate and as amended and passed by the House seemed to fall short of what was required for the protection of the public. It was grossly inadequate in its provisions relating to drugs and the medical profession. There was little to choose between the Senate and House provisions. The Senate and the House of Representatives, however, reconciled all their differences except that relating to the control of advertising. The Senate proposed to vest authority in the Department of Agriculture, with power to proceed against offenders through the ordinary channels of criminal prosecution and injunction. The House of Representatives, however, proposed to confer authority over the advertising of foods, drugs, therapeutic devices and cosmetics on the Federal Trade Commission, with its much slower processes. No compromise could be reached, and the bill failed of enactment.

Almost immediately on the convening of the Seventy-Fifth Congress, there was introduced at the instance of Senator Copeland of New York a food, drug, therapeutic device and cosmetic bill (S. 5, 75th Congress) based on the bill introduced by him in the Seventy-Fourth Congress but which, after having passed the Senate, failed in conference. The new bill was in many respects a stronger and better bill than the one that failed. With few amendments, it passed the Senate and at the present writing (March 28) is now pending in the House of Representatives, before the Committee on Interstate and Foreign Commerce. In the House of Representatives a food, drug, therapeutic device and cosmetic bill was introduced by Representative Chapman of Kentucky, similar to the bill that passed the House of Representatives and failed in conference in the Seventy-Fourth Congress, but not identical with it. This bill along with seven others relating to foods, cosmetics and drugs, and along with the Copeland bill that has come over from the Senate, is at the present writing pending before the Committee on Interstate and Foreign Commerce.

STATE LEGISLATION

A survey of state legislation in 1936 of interest to the medical profession was published in the AMERICAN MEDICAL ASSOCIATION

TION BULLETIN for December 1936. Throughout the year, when state legislatures were in session, reports of the activities of state legislatures, so far as they might have a direct bearing on the medical profession, were published in the news columns of THE JOURNAL. Hereafter such publication will be in the Organization Section of THE JOURNAL. The Bureau of Legal Medicine and Legislation was in constant correspondence with constituent state medical associations in those states to which such legislation related. The more important measures of interest to the medical profession are discussed later.

Health Insurance.—Bills proposing the establishment of systems of compulsory state health insurance were considered in New York and Rhode Island. Neither of these bills was enacted. Both were patterned closely after the bill described by its proponents as a "Social Security Bill for Health Insurance" but which is popularly known as the "Epstein Bill," because of the activities of one Abraham Epstein, the secretary of the American Association for Social Security, Inc., by which the bill was prepared, drafted and sponsored. During the current year, 1937, at the present writing (March 28), health insurance bills have been introduced in five states. The bills in four of the states are patterned after the Epstein bill. The bill in the fifth state, Washington, was patterned after the health insurance act adopted in 1936 in British Columbia but which is believed to be so unworkable that no attempt is being made to give it effect.

Narcotic and Hypnotic Drugs.—The uniform narcotic drug act, drafted by the National Conference of Commissioners on Uniform State Laws, with the cooperation of the Bureau of Legal Medicine and Legislation, was enacted in 1936, with little modification, in Mississippi. So far in 1937 the uniform act has been enacted in four states, Idaho, Minnesota, Montana and Wyoming, and is pending or was considered in nine other states. The act, in its original or somewhat modified form, is now in force in thirty-one states. A law, separate and distinct from the state uniform narcotic drug act, was adopted in Virginia in 1936, to prohibit the possession, sale, use, distribution or production of cannabis. The law provides, however, that it is not to be construed as applying to licensed growers or to licensed manufacturers of drugs and medicinal supplies, hospitals, registered wholesale and retail pharmacists, or to licensed physicians, dentists or veterinarians. A similar law has been enacted so far in 1937 by one other state, Arkansas.

No laws were enacted in 1936 limiting the retail sale or distribution of hypnotic and somnifacient drugs, such as barbituric acid derivatives, to sale and distribution on the prescription of a licensed physician, dentist or veterinarian. Laws of this type have been enacted in recent years in fourteen states, and 1936 was the first year since 1929 during which there was no legislation on the subject. At present writing bills of this type are pending in seven states.

Laws Relating to the Healing Art.—Because the Supreme Court of Arizona declared that the Arizona basic science act had never had the force of law, since it had been adopted as a referendum measure at an election other than a general election, and not at a general election as required by the state constitution, the Arizona legislature found it necessary in special session to reenact it. It was reenacted in such form as not to be subject to referendum. An important amendment to the Massachusetts medical practice act was adopted in 1936 requiring, among other things, that an applicant for a license to practice medicine, in addition to previous requirements, (1) have completed two years of premedical collegiate work, including physics, chemistry and biology, in a college or university approved by an approving authority created by the act, consisting of the secretary of the board of registration in medicine, the commissioner of education and the commissioner of public health, and (2), in effect, have received the degree of doctor of medicine or its equivalent from a legally chartered medical school approved by the approving authority. In the past the board had to accept the credentials of any legally chartered medical college. No osteopathic, chiropractic or naturopathic legislation was enacted in 1936. Much cult legislation has been introduced so far in the 1937 legislative sessions, but no important bill has been enacted up to the date of this writing (March 28). A bill to create a separate naturopathic practice

act passed both houses in New Mexico but was vetoed by the governor.

The Virginia law granting liens to hospitals treating persons injured through the negligence of others, on all rights of action, claims, judgments or compromises accruing to the injured persons because of their injuries, was so amended in 1936 as to grant such liens to physicians and nurses also under similar circumstances. So far in 1937 a medical and hospital lien law has been enacted in Washington.

Hospital Service Corporations.—Laws were enacted in Massachusetts and Mississippi in 1936 authorizing the formation of corporations to provide hospital care to their members or subscribers. The Massachusetts law contemplates that such corporations operate on a nonprofit basis, but the Mississippi law seems to permit such a corporation to operate for profit. Bills to permit the formation and operation of hospital service corporations have been introduced in eight state legislatures so far in 1937, with no enactments up to the time when this report was prepared.

Workmen's Compensation.—Legislation relative to occupational diseases was enacted in Illinois, Rhode Island and New York in 1936. In Illinois the act provides compensation for any occupational disease arising out of and in the course of employment. In Rhode Island the workmen's compensation act was so supplemented as to make compensable about thirty-one stated occupational diseases. The New York law making compensable any and all occupational diseases was amended so as to limit the compensation and medical treatment for which an employer is liable under it to a worker partially or totally disabled from silicosis or other dust diseases. Under a law enacted in Massachusetts in 1936 the liability of an insurer to furnish adequate and reasonable medical and hospital services is limited to the first two weeks after the occurrence of an industrial injury (and not after the beginning of incapacity, as the prior law provided) and in unusual cases or cases in which specialized or surgical treatment is required, in the discretion of the department, for a longer period. The new law also confirms the right of the worker to select his own physician.

So far in 1937 bills have been introduced in a number of states (1) to permit an injured workman to select the physician whom he desires to treat him at his employer's expense and (2) to extend the limits of liability of the employer for medical and hospital services rendered an injured worker. None of these bills have been enacted as yet. A workmen's occupational disease act practically identical with the Illinois act referred to has been enacted in Indiana in 1937. A great number of bills to make occupational diseases compensable are pending at this writing (March 28) in a number of other states.

MEDICAL AND HOSPITAL CARE FOR RESETTLEMENT ADMINISTRATION CLIENTS

The Federal Resettlement Administration is authorized to make grants to farm owners, farm tenants, share croppers, farm laborers, persons on the official rolls of the Resettlement Administration, Aug. 14, 1936, and other persons who on that date were living on farms and in farm areas and who, when last employed, received the major portion of their income from farm operations. Such grants take into consideration the employability of the grantee, ordinarily indicating potentiality for rehabilitation. His eligibility for relief is construed as having been established when it has been determined through personal investigation that his material and credit resources are inadequate to maintain health and prevent suffering (*Federal Register*, Aug. 18, 1936, p. 1296). In connection with these relief activities, the Resettlement Administration has endeavored to aid its clients in obtaining adequate medical and hospital care. Unable to pay physicians and hospitals directly for such care, the administration has endeavored to afford relief through loans to its clients wherewith to pay for it, or to corporations organized by or on behalf of its clients through which they might obtain loans for that purpose.

Because of the excessive number of persons in certain rural areas who in 1936, because of drought and dust storms, were unable to provide medical care for themselves and their dependents, the Resettlement Administration deemed it best to establish in North Dakota and South Dakota so-called farmers' aid corporations, through which clients of the administration

might obtain loans for medical and hospital purposes more conveniently than from the administration itself. Unfortunately, the articles of incorporation of these associations were drafted in such a way as to continue them far beyond any period within which specific farm relief in the states named can be regarded as likely to be needed and so as to give such corporations powers far beyond those necessary to enable them to carry on the activities for which they were supposedly created. The dangers inherent in these excesses were pointed out to the North Dakota State Medical Association and the South Dakota State Medical Association. Both of them, however, entered into agreements to cooperate with their respective farmers' mutual aid associations for limited periods.

In states other than North Dakota and South Dakota, the need for rural relief does not appear to have been so desperate. As a result the Resettlement Administration has endeavored to arrange with county medical societies for reduced charges for medical services rendered its clients, loans to be made by the administration to its clients to whom medical or hospital service has been rendered, with the understanding that the money so lent to the client shall be paid by him to the physician or hospital that rendered service. Properly safeguarded so as to prevent imposition on the medical profession by clients in rural areas who are able to provide for their own medical needs, this plan seems unobjectionable.

SILICOSIS

At the invitation of the Secretary of Labor, the Board of Trustees delegated the Director of the Bureau of Legal Medicine and Legislation to serve as a member of a committee to study silicosis with a view to recommending better preventive measures and measures for compensation. The committee has submitted its final report, which it is expected will soon appear as a public document.

The deliberations of the committee disclosed a strong desire on the part of the representatives of labor to limit state departments of health to scientific and technical advisory work and to vest in departments of labor all authority and responsibility for the administration of the laws and regulations relating to silicosis. In the end, the committee recommended that the control of silicosis be entrusted to a scientific body and an administrative body but left each state to determine for itself whether it will place both of these agencies in its department of health, or both in its department of labor, or one in one department and the other in the other department. It is obvious, however, that, other things being equal, a disinterested technically informed body, such as the state department of health, which stands neutral between employer and employee, can do more effective work than will be done by any lay agency that cannot escape the suspicion of being partisan, at least subconsciously, and inclined to favor the employee as against the employer. State departments of health, too, have the advantage of being correlated to analogous cooperating health units throughout the state; namely, municipal, county and district health departments.

Integration of the Medical Profession.—There have been no developments during the year looking toward the so-called integration of the medical profession in any jurisdiction, along the lines of organization recently adopted for the organization of the bars of the several states.

MEDICOLEGAL CASES: 1931-1935

The Bureau published in 1936 its second volume of abstracts of medicolegal court cases, containing abstracts that had appeared in *THE JOURNAL* during the calendar years 1931 to 1935, inclusive. This volume contains a table of cases and 813 pages of abstracts and carries, as did its predecessor, an adequate index by the use of which all major points of medicolegal interest involved in the abstracted decisions may be readily referred to by physicians, lawyers, claim adjusters and other users of the volume.

The Board of Trustees expresses its appreciation of the hearty cooperation given to the Bureau of Legal Medicine and Legislation during the past year by constituent associations and component societies and by many individual physicians.

Summary

1. *The United States Department of Health.*—The establishment of a Federal Department of Social Welfare

has been recommended by the President, to administer federal health, educational and social activities. Action intended to be helpful in preserving the integrity of medicine and the public health and to promote the creation of a Department of Health, independent of the proposed Department of Social Welfare, has been taken.

2. *Federal Health Insurance.*—The Social Security Board has been engaged in a study of social insurance, including health insurance. Indications are that the board will ultimately make an intensive study of health insurance. A bill, prepared by or under the direction of Abraham Epstein, is pending in the Senate Committee on Finance, proposing to establish a system of federal health insurance.

3. *Social Security Act.*—Physicians and medical associations are affected by the taxes imposed by the Social Security Act only to the extent that employers and employees generally are affected. A medical association may be exempt from the taxes if organized and operated exclusively for scientific or educational purposes and if no part of its income inures to the benefit of any private shareholder or individual. Application for exemption should be filed with the office of the Commissioner of Internal Revenue.

4. *Medical Services for Federal Employees.*—A bill pending in Congress proposes to accord to osteopaths equal rights with doctors of medicine in the treatment of federal employees under the United States Employees' Compensation Act. Protests against the enactment of this bill have been filed.

5. *Sale of Helium by the Bureau of Mines.*—The sale of helium to United States citizens or corporations by the Bureau of Mines is proposed to be authorized by a bill pending in Congress, which has the approval of the Secretary of the Interior and the American Medical Association.

6. *Contract Surgeons of the Spanish-American War.*—The injustice that has been done to contract surgeons of the Spanish-American War continues. Pending legislation to grant increased pensions to veterans of that conflict omits reference to contract surgeons although continuing recognition of other persons who rendered services no more meritorious.

7. *Food, Drugs, Therapeutic Devices and Cosmetics.*—In the Seventy-Fourth Congress, the Senate and the House were unable to compose their different views with respect to the federal agency to have jurisdiction over the advertising of food, drugs, therapeutic devices and cosmetics, and as a result legislation then pending to revise the federal food and drugs act died with the adjournment of the Congress. When the Seventy-Fifth Congress convened, a stronger and better bill, in many respects, than the one passed by the Senate in the Seventy-Fourth Congress was immediately introduced in and ultimately passed by the Senate. It is now pending in the House Committee on Interstate and Foreign Commerce along with other bills relating to the same subject matter. The outcome of this legislation cannot safely be prophesied.

8. *State Health Insurance.*—During 1936, bills patterned after the so-called Epstein bill were introduced in two states, to establish systems of compulsory health insurance. In 1937 to date (March 28) similar bills have been introduced in four states. In another state, a bill patterned after the British Columbia health insurance act has been introduced.

9. *Narcotic and Hypnotic Drugs.*—The uniform narcotic drug act, approved by the American Medical Association, was enacted with slight modification in one state in 1936. In 1937, to date, the uniform act has been passed in four states. It is now in force in thirty-one states, either in its approved or in a modified form. A law relating to the possession, sale, use, distribution or production of cannabis was enacted in 1931 in one state and a similar law has been enacted to date in another

state in 1937. Laws relating to the retail sale or distribution of certain hypnotic and somnifacient drugs have been enacted in recent years in fourteen states. Bills relating to such drugs are now pending in seven states.

10. Laws Relating to the Healing Art.—The Supreme Court of Arizona voided the basic science act of that state in 1936 on the ground that it had been improperly submitted to a vote of the people at a special election. The legislature, however, reenacted the bill. The medical practice act of Massachusetts, in 1936, was amended to impose a two years college educational requirement on applicants and to authorize a board consisting of the secretary of the Board of Registration in Medicine, the commissioner of education and the commissioner of health to pass on the credentials of medical colleges.

While no cult legislation was enacted in 1936, many bills of that nature are now pending in the legislatures of the several states. A bill providing for a separate naturopathic practice act passed both houses in New Mexico but was vetoed by the governor.

In 1936 the Virginia hospital lien act was amended to accord its benefits to physicians and nurses. In 1937 a medical and hospital lien law has been enacted in Washington.

11. Hospital Service Corporations.—In 1936 two states enacted laws providing for the formation of corporations to provide hospital care to their members or subscribers. Bills contemplating the formation and operation of such corporations have been introduced in eight state legislatures in 1937.

12. Workmen's Compensation.—In 1936 legislation relative to occupational diseases was enacted in Illinois, New York and Rhode Island, and in 1937 in Indiana. Many bills relating to the compensability of occupational diseases are pending in the legislatures at the present time.

A law enacted in Massachusetts in 1936 reaffirms the right of an injured employee to select his own physician but limits the liability of an insurer with respect to the furnishing of medical and hospital services. Legislative proposals are under consideration in a number of states to permit injured workmen to select their own physicians and to extend the limits of liability of the employer for medical and hospital services.

13. Medical and Hospital Care for Resettlement Administration Clients.—The Resettlement Administration, in connection with its relief activities, has endeavored to aid its clients to obtain adequate medical and hospital care through the medium of loans made directly to such clients or indirectly through corporations organized by and on their behalf. In North Dakota and South Dakota, because of severe economic stress in the rural areas, so-called farmers' aid corporations were formed by the Resettlement Administration through which relief clients might obtain loans for medical and hospital purposes. These corporations, however, were organized along lines that raised questions of utmost importance to the medical profession. In other states the Resettlement Administration has endeavored to arrange with county medical societies for medical services for its clients, at reduced rates, loans to be made by the administration to its clients to pay for such services. The latter plan, properly safeguarded, seems unobjectionable.

14. Silicosis.—The Director of the Bureau, at the invitation of the Secretary of Labor, served as a member of a committee to study silicosis. The committee recommended that the control of silicosis be entrusted to a scientific body and an administrative body but left each state to determine for itself whether these agencies are to be placed in the department of health or in the department of labor. A disinterested technically informed body can obviously do more effective work than can be done by any lay agency. The committee has submitted its final report, which will probably soon appear as a public document.

15. Integration of the Medical Profession.—There have been no recent developments looking toward the so-called integration of the medical profession along the lines or organization recently adopted for the organization of the legal profession of the several states.

16. Medicolegal Cases: 1931-1935.—The Bureau published in 1936 its second volume of abstracts of medicolegal court cases, containing abstracts that had appeared in The Journal during the calendar years 1931 to 1935, inclusive.

17. Medical Units in Reserve Officers' Training Corps.—In 1936 Congress restored medical units in the Reserve Officers' Training Corps.

18. Tax Payable by Medical Schools Under Harrison Narcotic Act.—A reduction from \$24 to \$1 a year was effected in 1936 in the tax payable under the Harrison Narcotic Act by universities, colleges, schools and laboratories using narcotic drugs for research, instruction and analysis.

19. Tax Free Alcohol for Charitable Clinics.—Clinics operated for charity were authorized by a law enacted by Congress in 1936 to obtain alcohol free from federal tax for use in such clinics.

Bureau of Medical Economics

The Bureau of Medical Economics during the past year has endeavored to set forth in the published reports of its studies more of the economic principles that should govern in various forms of medical practice.

UNIVERSITY AND COLLEGE STUDENT HEALTH SERVICES

The study of university and college student health services was completed and published in February 1936. Information was received by the Bureau from 298 institutions having a student health service; twenty-five institutions replied that they did not maintain such a service.

The information on which the Bureau report was based was taken from the schedules returned by 255 of the 298 institutions having student health services.

The conclusions drawn from the study of the available data are as follows:

1. There has been, during the last decade, a steady increase in the number of institutions maintaining student health services. The trend is definitely toward a single department for the administration of the continuously expanding personal medical services and health activities.

2. Conclusions pertaining to the financial advantages or disadvantages of an organization of medical services for students are rendered dubious by the inadequacy and inaccuracy of the financial records for student health services. The reported cost per student is not appreciably less than the cost for similar services in the private purchase of medical and hospital care.

3. There appears to be a surprisingly large amount of capital invested in buildings and equipment devoted to health and medical services for students. A few health services have shown that student medical care plans can be operated effectively and economically without large investments in buildings and equipment by utilizing the medical agencies and facilities of the community.

4. There seems to be a general tendency to develop health and medical services in colleges and universities on an institutional rather than a community basis. The extension of student health services into comprehensive plans disrupts the professional practice of medicine into a system of institutional medical enterprises. Under such plans the patient is considered as a member of a restricted cultural group rather than as a human being subject to his entire environment.

5. There is a growing belief that the place of the student health service in the community medical scheme should be that of an agency to supervise the health of students and to teach health standards.

6. Neither the organization nor the conduct of student health services appears to have followed any generally accepted principles or objectives except to provide students with some sort of health instruction and variable forms and degrees of medical advice and care. The essential pedagogic and medical factors in the health program seem to have suffered because of new activities of student health services without careful investigation of their usefulness and largely designed to advance athletics.

7. There seems to be evidence to show that the health education of students, which is presumably the primary function of a student health service, has not always been as effective as might be expected of institutions of higher learning. The health education program, which should enable college students to acquire health principles and hygiene practices that will influence public opinion and social custom for the betterment of human health, has been neglected because of unnecessary emphasis on the treatment and management of illness among the students.

8. A universally accepted measure of performance or accomplishment by which the programs and benefits of student health services may be judged has not been evolved. The lack of a proper method of appraisal has permitted a confusion of clinical and health educational activities to the detriment of the more widely beneficial education program. The evaluation of student health services may be made possible by properly prepared health records and health tests.

9. It appears that a large percentage of universities and colleges are actually engaged in the practice of medicine in varying degrees. The successful operation of a few student medical care plans in accordance with the ethical principles of the medical profession indicates that there are no insurmountable obstacles to so operating other student health services.

10. The segregation of a section of the medical profession by student health services under standards built on a compromise between the ideals of medicine and the interests of educational institutions is proving harmful to the educational institutions and to the medical profession alike. This division within the medical profession reduces its influence in molding the standards and ethics of these plans into a form which will best serve in the prevention and cure of disease.

11. The number of instances in which a practical cooperative arrangement has been effected between the college and the county medical society of the college community for the medical care of students seems to be lamentably small. It does not appear likely that the health education objectives of a student health service will be achieved until harmonious cooperation is established between educational institutions and the medical profession.

Many copies of the report of the Bureau of Medical Economics have gone to persons who are interested in or are directly connected with student health services. Since the publication of this report, some significant tendencies have been noted.

Information received from Pennsylvania, Texas, Illinois and Washington indicates that the directors of student health services are changing their attitude toward medical service for students. In one state a program for student medical service plans, adopted by the department of education and approved by the state medical society, has been put into effect by a college with the endorsement of the county medical society. The accepted program includes regulations governing medical services which are in accord with the principles regarded as desirable in the Bureau report. The Bureau has had occasion to refer committees from colleges to county medical societies for further assistance in reorganizing arrangements for student medical care.

The chairman of a committee for the National Conference on College Hygiene commented very favorably on the report and asked the Bureau to suggest standards for consideration at the conference. An outline of proposed standards, principles and regulations to be discussed by another committee at the conference was submitted to the Bureau. A careful analysis of these proposals showed a most encouraging willingness on the part of the committee to agree with the point of view of the medical profession with regard to questions of medical services in universities and colleges.

As was indicated in the report, it appears that student health services are in a transition stage and that a splendid opportunity exists for county medical societies to assist in the organization of student medical care plans. Success in arranging medical service plans for students will result in much progress along the road toward private practice and an ever better medical service.

GROUP HOSPITALIZATION

No development in the field of medical economics, with the exceptions perhaps of sickness insurance and state medicine, has aroused more interest and discussion than has group hospitalization, or prepayment plans for hospital care.

During the recent economic depression, hospital income from endowments and voluntary contributions was decreased by about two thirds, the charity load was increased almost four-fold, and huge obligations growing out of capital investments or fixed costs remained unmet. It is believed that such conditions induced many hospitals in the United States to adopt group hospitalization plans as a means to secure needed income. The sponsors of these plans have offered them as a method of providing low cost hospitalization and have urged hospitals all over the country to adopt them.

A study has been made of the experiences of the majority of group hospitalization plans. The subject matter of the

report will be arranged according to the following main headings:

Introduction.

The Background of Group Hospitalization.

The Development of Group Hospitalization Plans.

The Status of Group Hospitalization Plans.

Insurance and Group Hospitalization.

The Relation of Group Hospitalization Plans to the Practice of Medicine.

Guiding Principles and Conclusions.

At the time this report was prepared there were fifty-six operating and thirty-four proposed group hospitalization plans that were being actively promoted. These ninety plans are all that remain active out of some 172 surveyed. This indicates a strikingly high mortality for group hospitalization plans. Some 469 hospitals were reported to be participating in plans in operation or proposed. At present the best estimate that can be made from available membership reports indicates that about 700,000 persons have become members of these schemes. Subscribers and their dependents are included in the membership reports in most instances. The number of subscribers—those who have actually signed their names to contracts and pay membership premiums for hospital insurance—is estimated to be about 500,000.

The number of these projects or the size of the membership is not the most significant development in the group hospitalization movement. The most important factor in this new method of marketing hospital services lies in the influence that it has on the relation of hospitals to medical practice. The hospital service contract seemingly cannot be limited to the provision of essential hospital facilities. With few exceptions, the contracts include medical services in one form or another. The practice of clinical pathology, anesthesia, radiology and physical therapy are a part of the practice of medicine. These services are medical services, whether performed by hospital employees under the direction of salaried physicians or by physicians who are practicing privately and have no contractual arrangement with hospitals. Whether physicians are salaried or not, they are governed by the Principles of Medical Ethics, which includes the principle that:

It is unprofessional for a physician to dispose of his professional attainments or services to any lay body, organization, group or individual, by whatever name called, or however organized, under terms or conditions which permit a direct profit from the fees, salary or compensation received to accrue to the lay body or individual employing him. Such a procedure is beneath the dignity of professional practice, is unfair competition with the profession at large, is harmful alike to the profession of medicine and the welfare of the people, and is against sound public policy.

If the profession encourages group hospitalization plans that include medical services, it cannot consistently object to hospitals profiting from the services of physicians when other special medical services are added to group hospitalization contracts.

The Bureau has repeatedly directed attention to the fact that group hospitalization is actually a form of insurance coverage. The determination of actuarially sound bases for premium rates, the careful selection of risks and the wise handling of funds are insurance duties that cannot be lightly undertaken by the inexperienced. The organizers of group hospitalization plans have accepted as probable experience that 10 per cent of the members will be hospitalized for an average stay of ten days, or that one patient-day per member annually will have to be provided. The rates charged subscribers and the payments to member hospitals are usually based on this expectation. The plan of group hospitalization has less reliable actuarial computations than health and accident insurance, which is notoriously unstable. Health and accident insurance companies have found that "the average person with a new form of insurance policy does not become 'insurance conscious' until he has had his policy a year or two—then the claims start to come in." The financial security of hospital insurance will depend on a more accurate estimate of anticipated losses than seems possible at present. Already it appears that certain groups, such as hospital employees, nurses, employees of physicians, women and adult dependents, are unusually hospital minded. Recently there has been a noticeable adoption of restrictions in hospital service contracts to prevent impending excessive hospitalization. On the other hand, some of the most ardent

proponents of hospital insurance schemes take the position that premium rates must be reduced. The indications from the schedules that have been returned are that hospitalization under group plans will be greater and the patient stay will be slightly shorter than expected. If the future financial security of these plans is at all doubtful, they should not now be held out as a solution to the financial ills of hospitals.

The financial balance sheets of some hospital insurance schemes may be deceptive. There appears to be a growing belief that these schemes are accumulating appreciable reserves. On the basis of total income, several plans have reported surpluses. If, however, hospitalization costs and administrative and promotional expenses are deducted from the *earned* income, surpluses would, in some instances, be materially reduced and apparent profits might be transformed into losses. A few of the better managed plans do report actual surpluses, but even these amount to less than \$2 per member, whereas a conservative reserve would be \$5 per member.

There appears to be a current attitude that reserves are unnecessary because member hospitals always stand ready to render services. However, since hospitals usually contract to render service only on the payment of a specified per diem rate, it is essential that funds be available when members of the plan need hospital care. At the present stage of hospital insurance schemes the question of the liability of member hospitals to provide service under the contract, if the funds of the plan should become exhausted, has not yet been determined. It is believed that greater security could be provided for members by guaranteeing both the available facilities of member hospitals and an adequate cash reserve.

During the present period of rapid membership growth, a low loss ratio can be expected. However, as the membership grows older and it becomes more difficult to obtain new members in groups large enough to avoid adverse selection, an increase in the number of persons hospitalized and in the costs of hospitalization will be probable. Thus, when the membership of these plans reaches a stationary point or begins to decline, an increase in the hospitalization of members and in costs can be expected. The actuarial basis for each plan will then require close scrutiny. If such developments occur, those plans which have ignored the setting up of reserves will be in a particularly hazardous position.

The new plan for group hospitalization is too often considered as a device to fill vacant hospital beds and to augment hospital income. These plans were originally supposed to be a method of assisting persons with limited means to secure necessary hospital services. It would therefore be assumed that such services should be rendered at less than regular rates. Accordingly, there should be some income limitation, at the "comfort level" of the community, to exclude those persons able to pay fair rates. If no concession in rates is made, that is, if the hospital continues to receive full fees for services rendered, there may be little justification in insisting on an income limitation for those who may subscribe. If the hospital continues to receive regular rates under the group hospitalization plan, the plan simply becomes a method for selling hospital service on a prepayment basis and the altruistic purpose is entirely lost. The value of the group hospitalization plan will then be determined by the answer to the question "Is it worth while to create an institution to provide hospitalization on a prepayment arrangement for hospital bills when the administrative costs are some 12 to 40 per cent of the patients' fees?" It is believed that a postpayment plan for those persons really unable to meet their hospital bills would be more economical. In a number of communities, county medical societies have created facilities whereby persons having low incomes may secure medical and hospital care at reduced rates on a deferred payment plan. The cost of administration of such plans is about 10 per cent, which is borne by the physicians and the hospitals. No interest, carrying charges or credit rating costs are added to the patient's bill. In the last analysis public opinion will decide which plan is wanted, but all persons should be entitled to the facts without the coloring of bombastic claims.

Available information indicates that there has been an increase in the number of persons seeking free hospital care. When considered in connection with the incomes of American workers,

this increase does not appear to be entirely warranted. It is claimed that hospital insurance schemes will meet the needs of the low income group and will remove them from tax-supported hospitals and the free services of private hospitals. Group hospitalization plans are ostensibly intended for the benefit of population groups on which full hospital fees would prove a hardship. However, it is often stated by the proponents of hospitalization insurance schemes that membership has not yet reached the rural and low income groups. These proponents believe that the premium rate is an obstacle in many cases. While the cost for a single membership is usually about \$9, the annual cost for a family may be as high as \$40. The relief from this dilemma will require serious study. A hospital routing plan, based on a central admitting bureau which determines the ability of patients to pay hospital bills, is a more direct solution to the problem of the abuse of free hospital services.

Group hospitalization plans at best will serve but a small percentage of the eligible population. They make no provision for the care of the indigent, those above certain age limits or those otherwise excluded, and only slight provision for the chronically sick and the unemployed. They must not, therefore, be permitted to develop features antagonistic to the private practice of medicine, which is maintained to provide for the medical needs of all persons regardless of income status, nature of illness, age, membership in some social group, or any other such artificial classification.

The Bureau of Medical Economics has consistently maintained that the decision as to whether or not a group hospitalization plan is essential must rest primarily with the medical profession and the hospital officials of the local community. Furthermore, if it is decided that a group hospitalization plan is necessary to complete or to augment the existing hospital facilities of the community, certain principles of organization and administration should be observed. The following principles are suggested in the interest of fairness, efficiency and greater security, and in the event that hospital insurance is deemed necessary:

1. The plan of organization should conform to state statutes and case law. The majority of the governing body of the hospital insurance plan should be chosen from among members of official hospital groups and members of medical societies. Great care should be taken to assure the nonprofit character of these new ventures.

2. The plan should include all reputable hospitals. The qualifications of the participating hospitals should be closely supervised. Member hospitals should be limited to those on the Hospital Register of the American Medical Association or to those approved by the state departments of public health or other state agencies in those states in which there is approval, registration or licensing of hospitals.

3. The medical profession should have a voice in the organization and administration of the plan. Since hospitals were founded to serve as facilitating means to the practice of medicine, the medical profession must concern itself intimately with plans likely to affect the relations of hospitals to physicians.

4. The subscriber's contract should exclude all medical services—contract provisions should be limited exclusively to hospital facilities. If hospital service is limited to include only hospital room accommodations such as bed, board, operating room, medicines, surgical dressings and general nursing care, the distinction between hospital service and medical service will be clear.

5. The plan should be operated on an insurance accounting basis with due consideration for earned and unearned premiums, administrative costs and reserves for contingencies and unanticipated losses. Supervision by state insurance departments has been advantageous for both the buyer and the seller of insurance contracts. Laws permitting the formation of hospital service corporations should not remove the benefits of such supervision nor violate the principles enumerated.

6. There should be an upper income limit for subscribers. If group hospitalization plans are designed to aid persons with limited means to secure hospital services, they should render such service at less than regular rates. If no consideration in rates is made for persons with limited means, group hospitalization plans lose their altruistic purpose and there may be little justification for an income limit.

7. There should be no commercial or high pressure salesmanship or exorbitant or misleading advertising to secure subscribers. Such tactics are contrary to medical and hospital ethics and are against sound public policy.

8. There should be no diversion of funds to individuals or corporations seeking to secure subscribers for a profit. The moment hospital insurance loses their traditional character as institutions of charity and humanitarianism the entire voluntary hospital system will break down.

9. Group hospitalization plans should not be utilized primarily or chiefly as means to increase bed occupancy or to liquidate hospital indebtedness. Such plans, if they are necessary, should place emphasis on public welfare and not on hospital finances.

10. Group hospitalization plans should not be considered a panacea for the economic ills of hospitals. They can serve only a small portion of those persons needing hospital services. Hospitals must continue to develop efficient methods of administration and service independent of any insurance method of selling their accommodations.

Notwithstanding the efforts of medical societies and this bureau, as well as the reports of the Judicial Council and the action of the House of Delegates on group hospitalization at the Kansas City session to develop principles for the guidance of the group hospitalization movement, few, if any, of the plans exclude all medical services from their group hospitalization contracts. The extent to which medical services are included in the hospital service contracts is shown in the report of the Bureau.

For many years there have been serious discussions among physicians and hospital administrators concerning the most equitable arrangements for anesthesia, clinical pathology, radiology and other special medical services in hospitals. These are fields in which hospitals and the medical profession must seek and apply adjustments. Just now, when a more satisfactory relationship in some of these fields seems to be in view, group hospitalization tends to accentuate and perpetuate the very conditions which the medical profession and some hospital authorities have sought to improve. Hospital insurance plans tend to force the continuation of undesirable practices and relations between physicians and hospitals.

These prepayment plans for hospital care show a distinct tendency to place hospitals themselves in the field of medical practice. If group hospitalization organizations become sufficiently strong in membership support, and if they pursue the announced policy of liberalizing benefits, the future course of such plans seems clear. Either they will offer a longer period of hospital stay, or they will include more medical services. It is only occasionally that patients need more than the twenty-one days of hospitalization now offered. At the time of hospitalization every patient needs one or more medical services. Who can deny that the directors of these schemes may propose to include additional medical services to make their contracts more salable? There is only a remote possibility that a future development in these plans will be a decrease in subscription rates.

If group hospitalization schemes were to confine their benefits strictly to hospital facilities, the movement would avoid most of the undesirable disturbances in the field of medical practice without impairing the value of the plan as a method of assisting persons with limited incomes to receive hospital services. In this connection there is need for a thorough understanding on the part of the organizers and administrators of group hospitalization plans as to what constitutes medical services.

Because of the several reasons outlined, group hospitalization, instead of preventing the advent of some form of sickness insurance, is more likely to be the first step toward the opening of hospitals for all persons in the community and then a system of state managed medicine. The group hospitalization movement is clearly one of the major issues demanding action by the medical profession if the future of medical practice is to be maintained on a basis which guarantees that the welfare of the sick individual is the first consideration.

ECONOMICS AND THE ETHICS OF MEDICINE

In June 1936 the Bureau published a discussion of the relation between economics and the Principles of Medical Ethics. The publication contains five chapters:

- Chapter I. The Hippocratic Oath.
- Chapter II. The Principles of Ethics of the American Medical Association.
- Chapter III. The Relation of Ethics to Economics.
- Chapter IV. The Development of Medical Ethics.
- Chapter V. The Medical Group.

Many of the principles of medical ethics contain economic implications. This discussion is intended as much for the medical student as for the practicing physician. It is hoped that some explanation of these principles may serve to emphasize that many of the problems which are often thought to be economic are in reality ethical.

CARE AND RELIEF OF PHYSICIANS AND THEIR DEPENDENTS

The Bureau has prepared a synopsis of the existing state or county medical society pension or relief plans for indigent physicians. This summary appeared in the November BULLETIN. In this article there is also a discussion of the organizations which have been created in foreign countries for the care and relief of physicians and their dependents.

The conclusions drawn from the Bureau's study of this subject are:

1. From all present indications of actual need, it would be impracticable to organize a national "Benevolent Society" or "Relief Fund" under the auspices of the American Medical Association. State and county medical societies have often indicated that there are but few instances of indigence. A report of the Works Progress Administration shows that of the 82,000 professional and technical workers on relief 675 were "physicians, surgeons and dentists." This number may be compared with 20,000 teachers, 15,000 musicians and music teachers, 6,800 nurses, 6,200 engineers, 4,500 draftsmen, 3,800 actors, 3,000 clergymen and religious workers, 2,900 artists, 800 chemists, assayists and metallurgists, and 1,400 reporters and editors. Until it can be definitely shown that there is now a real need for a national relief fund, the state and county medical societies should be encouraged to develop benevolent activities according to local requirements. Not until the burden of benevolence tends to become too large for local resources should a national fund be established.

2. Few of the proposed projects for the establishment of new homes or clubs for aged physicians deserve encouragement. While the philanthropic motive behind such movements is commendable, it should not be permitted to confuse the fact that these plans have been repeatedly disavowed as an uneconomic and unsatisfactory solution of the problem of caring for aged physicians. Homes now in existence can satisfy the demands for facilities to accommodate aged physicians desiring or needing institutional care. Certainly it does not appear to be within the province of the American Medical Association to establish new homes.

3. Commercial insurance companies have so improved their contracts and rates that it is questionable whether any mutual assessment association to be newly organized could offer a similar contract with the same guaranty of good management, resources and services. It would not now be advisable for the American Medical Association to enter into the insurance business.

4. The formation of an agency to secure more advantageous insurance contracts and reductions in premiums—in effect, a wholesale insurance buying arrangement—which is said to operate effectively for several European medical associations, might, in time, become adaptable to the circumstances in the United States. Through its Bureau of Medical Economics, the American Medical Association has given a great deal of service on all matters pertaining to insurance. The advisability of creating an intermediary insurance purchasing agency for physicians would require careful study.

RURAL MEDICAL SERVICE

Are rural sections of the United States suffering from a lack of available medical service? If so, where are they and what are the conditions responsible for such deficiencies?

The Bureau of Medical Economics, with the assistance of the state medical associations, has undertaken an investigation to obtain the facts needed to answer these questions. The first step was to locate the counties with the largest population per physician. While making all possible allowance for the fact that a county is by no means a social or medical unit, it is the unit of nearly all available statistical compilations. It is also recognized that the ratio of population to physician is far from being an exact measure of available medical services. The most that can be claimed for such a ratio is that it is an indication of the extent to which such services are available.

Even a superficial examination of the medical writings of the last 100 years will indicate that there has scarcely been a time or a place, in Western nations at least, when there have not been complaints of a lack of medical service in rural districts. Moreover, the extent and vociferousness of these complaints seem to bear no particular relation to available medical facilities, unless, as sometimes appears probable, the complaints become more vocal as the facilities increase.

In 1918 there were 123 counties in the United States with more than 2,000 persons per physician. This number had increased to 297 counties located in thirty states in 1934 and had dropped to 233 in 1936. According to the American Medical Directories, there were sixteen counties in 1934 and nineteen counties in 1936 having no physicians. The sparse population of these counties is apparent. Seven of the counties in 1934 and ten of the counties in 1936 were included in the jurisdiction of county medical societies.

The detailed analysis of the economic conditions in each of the states having four or more counties with 2,000 persons per physician has appeared in THE JOURNAL and will soon be available in reprint form.

† U. S. Dept. of Commerce. Fifteenth Census of the United States, 1930.

Measures that may be helpful in relieving an apparent shortage of medical facilities in one community may be inappropriate for another. Any relief must be based on a careful evaluation of many local factors. Some of these factors are:

- Density of population.
- Productive characteristics of the area.
- Annual spendable income per capita.
- Distance to surrounding medical facilities.
- Characteristics of terrain.
- Transportation and communication facilities.
- Degree to which the local population appreciates the need for and value of good medical care.
- Actual amount of money necessary to maintain good medical facilities.
- Extent to which the community is not only able but also willing to support medical accommodations.

It is generally understood among physicians that about 85 per cent of all illnesses can be managed safely and satisfactorily in the home. About 15 per cent of all illnesses are sufficiently serious or complicated to warrant hospital care, if available, both for the welfare of the patient and for the easier application of modern methods of diagnosis and treatment that are afforded the attending physician.

Complaints have come from some rural organizations concerning the mileage charge in certain sections of the country. Conditions affecting transportation differ so widely that the application of a universal rule concerning mileage may be impossible. This, however, is a question for study by state and county medical societies within their jurisdiction. It is possible that some adjustment of fees for certain rural areas might do much to relieve the problem of rural medical service.

Various methods of providing medical facilities for rural districts have been proposed; some have been tried. Some have advocated that the physician be guaranteed a specified income. Such plans, in those places in the United States where they have been used, have survived for only a short time. Small hospitals for rural areas are of no value unless competent physicians are available to provide good service. Areas with sparse population could not support a hospital or a physician.

This subject deserves further careful study.

COOPERATIVES, RESETTLEMENT PLANS AND OTHER NEW FORMS OF MEDICAL PRACTICE

Requests are coming to the Bureau for information concerning the attitude of the American Medical Association toward some of the new forms of medical practice now being proposed

in different sections of the United States. The Bureau has confined its activities to the collection of data pertaining to medical economics, the criticism of methods and plans used in the practice of medicine, and the formulation of principles that should govern in good medical practice. Although the Bureau has not yet received documents descriptive of the exact nature and scope of all these new proposals, it is anxious to secure complete information concerning any new movement affecting the practice of medicine.

It appears that there is a steady increase in the number of plans seeking to arrange medical services for those with low incomes. These are now taking the form of benefit associations, cooperatives and corporations. The methods of financial support of these organizations are by membership dues or, in the case of the Resettlement Administration, by loans to clients. Payment for medical services is either on the basis of a prearranged fee schedule or by a fixed salary.

The Rural Resettlement Administration has developed plans for medical care which have been submitted to several state medical societies by the medical officer representing the administration. Two of these plans are given here as presented by the Rural Resettlement Administration.

TENTATIVE PLAN

A proposal for emergency medical care for the 32,000 (approximate) destitute or low-income farm families in Missouri who are Resettlement Administration clients is outlined herewith. The final plan agreed on is to be approved and recommended by the Missouri State Medical Association.

1. Each county medical society will appoint a committee to make contact with and work in cooperation with the county rehabilitation supervisors. This committee from the county medical society may review the list of low income farm families who are the responsibility of the Resettlement Administration in order to obtain information as to who constitute the Resettlement Administration clients in a county.
2. Rural rehabilitation supervisors will canvass their clients and have each family choose the physician who is to be used in case of illness.
3. The Resettlement Administration clients in each county will organize a County Farmer's Aid Association, each member of which will apply to the Resettlement Administration for a loan of \$25 to provide emergency medical care for one year. The County Farmers' Aid Association will elect a treasurer, who will be bonded. This treasurer may be any responsible person in the community. When the loan of \$25 is received by each family, these funds will be placed by the treasurer, to the credit of the County Farmers' Aid Association, in a local bank. Only destitute and low income farm families who are the responsibility of the Resettlement Administration will be eligible for membership in the County Farmer's Aid Association.
4. Physicians in the county who accept the plan will render home and office medical care, including antepartum and obstetric care and ordinary drugs, to Resettlement Administration clients as required. It is expected that the minimum service will be rendered that is consistent with the welfare of the patient. The bill for such services will be rendered to and paid by the treasurer of the County Farmers' Aid Association.
5. A special schedule of fees for Resettlement Administration clients will be agreed on.
6. Special arrangements will be required for hospitalization and surgical operations and shall not be construed to be a part of this plan. A special fee schedule will be agreed on for this service.
7. The advisory committee of the county medical society, on request of the treasurer of the county farmers' aid association, will review such bills for medical care as may seem necessary.
8. This plan will be effective for one year.

TYPES OF ACCEPTABLE COMMUNITY AND COOPERATIVE SERVICES
March 27, 1936
Missco Community Cooperative Medical Association

One hundred and twelve rural rehabilitation clients have organized the Missco Community Cooperative Medical Association in order to provide services of a physician and medicine for themselves on an annual basis.

Each client obtained an individual loan of \$30 from the Resettlement Administration to participate in the service.

The president, vice president and secretary-treasurer of the association comprise the board of directors, who retain a competent physician to provide medical service; \$3,300 for physician's salary and medicine is authorized.

Membership privileges include:

- (a) An annual physical examination.
- (b) Such medical care in home and office as is usually given by a general practitioner, including preventive service for the most prevalent and common diseases (diphtheria, smallpox, typhoid fever, scarlet fever).

- (c) Medicine for the treatment of ordinary diseases in an amount not to exceed \$10 in value for each family. The physician will be reimbursed if he furnished this, or the secretary-treasurer may purchase medicine.
- (d) An additional \$5 fee shall be required for each obstetric case.
- (e) Excessive night calls shall not be required.
- (f) In case of a dispute between the doctor and a member, the county supervisor shall arbitrate.

Loans made for participation in the medical service are repaid from income as shown on regular farm and home plans. All client-members live within a six mile radius.

SUGGESTIONS

This division has made the following suggestions to the regional director with respect to this application for guidance in the further development of this type of project:

1. We are also of the opinion that, instead of the flat amount (such as \$30 per family regardless of the size of the family) there should be a minimum charge of not less than \$1.50 per month per family, and a maximum charge of not to exceed \$5 per month per family, with a small fee for additional members over and above a specified number. A family of say three or four members should not be charged the same as a family of ten or twelve. The additional fee might be as small as 15 cents or 20 cents or as high as 50 cents for each individual member, but in no event should the total amount charged to each family exceed the maximum referred to.

2. There may be some instances in which the medical associations would be justified in contracting with a group of doctors, in case they are available, in order that members of the association will have some choice in the selection of the doctor. There may be times when one doctor is unable to serve the needs of the entire group. In such instance, it would be all the more important to be able to employ the services of several doctors.

3. The contract with the doctor, or doctors, should specify clearly the amount paid either monthly or annually.

Some other plans of the Rural Resettlement Administration involve elaborate, complicated and exceedingly broad articles of incorporation which are vague on several important points, as to those who may claim benefits, the period over which the corporation is to operate, the right of clients to choose their own physicians and the profit or nonprofit nature of the organization. The attention of the administration has been called to these and other points which need to be clarified.

Some confusion has been created by designating the Resettlement medical plans as "cooperatives." There is practically no resemblance between these schemes and the cooperatives which are organized on the principles of the Rochdale cooperative plan.

Greater confusion is likely to result from the proposals that are now emanating from the Bureau of Cooperative Medicine. Of the six plans offered by the Bureau of Cooperative Medicine, one is given here:

THE A PLAN

This plan provides complete medical service and hospitalization from the beginning and does not involve partial medical service set-ups.

Money is raised to subsidize the setting up of a Central Medical Group, including equipment, hospital arrangements and guaranty of salary for the Central Specialist Group for three years (from one donor or many makes no difference).

The money raised to provide the subsidy is now returned to the donor and replaced by the aggregate capital funds raised by the sale of bonds. (Initiation fee certificate.)

Interest in the subject is continued by a purely educational program conducted from the Bureau, and when the central specialist set-up is ready, then the "co-ops" are admitted so far as is possible using their own general practitioners in their localities and the already trained specialists at the Central Medical Group.

This Central Medical Group remains as a training school for professional and lay personnel, who will soon be needed to service additional "co-ops."

The Central Medical Group consists of the following:

A centrally located medical center with all the apparatus necessary to make accurate diagnoses.

The offices and consulting rooms of the various specialists as well as a library and a meeting room for consultations, discussions, the reading of papers, and other purposes.

A completely equipped diagnostic laboratory.

A completely equipped x-ray department ready for both diagnosis and high voltage therapy. These facilities will be available to the hospital, so that they need not be duplicated.

Adequate ambulance equipment to transport all hospital cases to the hospital (to be discussed).

A staff of full-time doctors (male and female), who will represent the various phases of medical practice in such a manner that each is practicing that part of medicine for which he is best fitted. Salaries to range from \$350 to \$1,500 a month net.

Hospital facilities sufficient for the ample and unrestricted hospitalization necessary for a membership of at least 50,000.

Administrative officers and offices.

Each unit should have about 50,000 members (Ross-Loos experience).

About fifty-five doctors to service this group.

All physicians are on a full-time salary basis.

Each family is considered to be husband, wife and two unmarried, dependent children under the age of 18 domiciled in the household.

The original stake for each family will be \$50, of which \$20 will be payable on application and \$15 at the beginning of the next year, and the balance of \$15 at the beginning of the second year. In the event that hospitalization is necessary, the entire balance due must be paid in.

The monthly dues will be graded. The first member of the family will pay \$3, the second \$2.75, and any of the unmarried dependents (children under 18) will pay \$1.75. Since the average family consists of husband, wife and two children, their dues will be \$9.25 per month, an average of \$2.50 per person.

On an individual basis, the monthly dues will be \$2.50 per person.

Average stake \$12.50 per unit of membership.

Individually (unmarried adults), admission is at \$50 stake and \$3 per month.

Family incomes range from \$2,500 to \$4,000.

Considered individually, the income group would be between \$800 and \$1,200 a year.

Certain people will be willing to make sacrifices in order to join these "co-ops" just as truly as certain will make condescensions.

As soon as enough experience has been accumulated, the expense could be lowered by using less expensive locations or buildings but not cheaper medical skill.

The availability of this type of plan could be increased by allowing the government or employer to assist the low income groups to pay dues—paying part of their dues from public or industrial funds. These low income "co-ops" could serve as training grounds for younger physicians.

Test groups should be put into operation in three different locations: a metropolitan area with its cosmopolitan population, a set of people under similar employment regulations such as government employees, city employees, Consolidated Edison, and a rural area.

The payment of a nominal interest on the original stake might prove a good feature and could be determined by the L. B. M.

This proposal would introduce a type of medical practice only slightly different from club practice and voluntary insurance. There is nothing essentially "cooperative" about it. It seems safe to assume that the introduction of such a scheme would tend to encourage the spread of other schemes strikingly similar to the "club practice" which filled England prior to 1911.

Wherever the cooperatives have used their financial resources and their organization machinery to build up club medical practice, the resulting tendency has been to supply their members with an inferior form of contract medical service. This has been true in this country in the few instances in which attempts at such "cooperative" organization have been made. Any cooperative that would follow a similar policy with regard to distribution of food would be at once condemned by a sincere cooperator. Such proposals gain a hearing only because cooperators are no more able than the rest of the lay public to judge of the quality of medical service.

The creation of new methods of distributing or providing medical services does not call for new and different principles of administration. The element of greatest importance both to the sick person and to the medical profession under any plan is the quality of service. In the principles of medical ethics, the medical profession has a means of safeguarding quality if there is adherence to these principles. Principles of medical economics are being formulated as rapidly as possible. However, under no circumstances must the economic phase of medicine be permitted to assume the primary position that has always been held by medical ethics.

The House of Delegates at the Cleveland session in 1934, and again at the Special Session in February 1935, stated its position with respect to new methods of organizing medical services. These actions still stand as the policy of the American Medical Association. It is of paramount importance for the profession to understand the implications in many of these new proposals, involving as they do the future practice of medicine. Specifically, the purpose and scope of any new plan should be clearly stated. If a plan is proposed for those with low incomes, a limit should be placed on those who may participate.

The medical profession holds that members of "cooperatives" and clients of the Federal Resettlement Administration, no less than other citizens, should be allowed the freedom to choose their own physicians; that there should be a minimum of administrative machinery, and that "bidding" for the care of the sick is inconsistent with the practice of ethical medicine. Some medical societies have created machinery for adjusting complaints and dissatisfaction over medical service and charges;

other societies might well consider the advisability of creating similar machinery. Many plans now being formulated may easily be changed to provide for a staff of salaried physicians and thus will deny to members the freedom to choose their own medical advisers.

Regimentation, regulation, red tape, limitation of choice, compensation by salary, and administration by nonmedical personnel are characteristics of systems of state managed medicine. These characteristics may not all appear at once, but each new proposal should be examined with great care to detect tendencies, implications and hidden phrases which may have grave effects on the future of medicine.

The obligation to treat the sick carries with it an obligation to maintain and improve the scientific methods used in medicine and also to resist those tendencies and influences which would destroy the quality of medical care and ultimately the institution of scientific medicine.

The House of Delegates of the American Medical Association has established certain principles for the guidance of medical societies when they undertake to study and evaluate such matters.

ORGANIZATION OF MEDICAL SERVICES

The Bureau undertook in 1936 to secure from a few medical societies a description of their complete program of activities. A prepared account of the several phases of the work of the county medical societies studied was submitted to each secretary for corrections and additions or deletions. The published descriptions of the activities of these county medical societies appeared in issues of the AMERICAN MEDICAL ASSOCIATION BULLETIN and are now available in reprint form.

It is not claimed that these descriptions represent a typical county medical society program but they do show that it is possible for many medical societies to develop a balanced and comprehensive program of activities beneficial alike to the public and to the medical profession. Some of these activities are: education on the importance of preventive medicine; improvement in arrangements for the care of the indigent sick; cooperation with boards of health and education and with hospitals in the proper allocation of responsibilities and the correction of alleged abuses; organization and coordination of available facilities for low income groups and the provision of additional facilities when needed; conduct of graduate education for practicing physicians; operation of credit and collection bureaus and physicians' telephone exchanges; maintenance of speakers' bureaus, and efforts to protect the public and professional interests in proposed legislation.

All these and other activities require the constant application of the Principles of Medical Ethics and careful study of details in order that methods of medical practice may be made to conform to good public policy.

Summary

It appears that a large percentage of colleges and universities are actually engaged in the practice of medicine. The health education program, in most institutions, seems to have been overshadowed and neglected because of the greater attention given to the clinical and curative phases of student health services. A few educational institutions are confining the activities of their student health services to health supervision and health education; these institutions are utilizing community medical facilities when needed. It seems likely that the health education objectives of student health services will be more readily achieved by establishing a harmonious cooperation between educational institutions and the medical profession. State and county medical societies should welcome the opportunity to assist colleges and universities in arranging an appropriate medical service.

Group hospitalization, as a method of prepayment for hospital care, is being actively promoted throughout many parts of the United States. Actuarial data on which to base sound premium rates are not available. Benefits under these schemes are not limited to low income groups. These schemes often include those who are able to pay fair hospital charges and they have thus far failed to reach a large proportion of the rural

and low income population. Most contracts for hospital facilities include some medical services. Hospital insurance schemes tend to accentuate and perpetuate the very conditions which the medical profession and hospital authorities have sought to improve. There appears to be danger that these schemes may include an increasing amount of medical service and thereby place hospitals in the actual practice of medicine.

The hospitalization insurance movement is one of the major issues before the medical profession. Some action is needed to safeguard the security of the plans and to guarantee that the welfare of the sick individual continue to be the primary consideration.

Many problems that confront medicine today are more ethical than economic. Proposals in the field of medical economics should be tested by the principles of medical ethics.

Present evidence seems to indicate that it would be impracticable to organize a national "Benevolent Society" or "Relief Fund" for indigent physicians under the auspices of the American Medical Association. Few of the proposed projects for the establishment of new homes or clubs for aged physicians deserve encouragement. Institutions now in existence can satisfy the demands for facilities to accommodate aged physicians who need or desire institutional care. It seems inadvisable for the American Medical Association to enter the insurance business, although the formation of an agency to secure more advantageous insurance contracts and reduction in premiums might in time become advisable. Such a venture would require very careful preliminary study.

There has scarcely been a time or a place in Western nations during the last century when there have not been complaints of a lack of medical service in rural districts. Reports from sources outside the medical profession of the number of counties having no physicians have been greatly exaggerated. There were only nineteen such counties in 1936. There were, in the same year, 233 counties having a population of 2,000 or more persons per physician. It is recognized that the ratio of population to physician is far from being an exact measure of available medical services. Relief of the shortage of medical facilities for rural communities requires careful study.

The number of new proposals for the organization and distribution of medical services to special population groups is rapidly increasing. These new schemes are taking the form of corporations, mutual benefit associations and cooperatives. They appear to give primary consideration to the methods of payment for medical services. The quality of service and the medical ethics involved are given subordinate consideration, if they are mentioned at all.

There appears to be a tendency in these schemes to favor the employment of salaried physicians and thus to limit freedom of choice. In some instances the cooperation of state and county medical societies has been sought. This appears to be a field in which medical societies should exert their best efforts to maintain high quality of ethical medical service to all sections of the population at fair fees.

Information from several county medical societies indicates that it is possible for these societies to develop and maintain a balanced and comprehensive program of activities beneficial alike to the public and to the medical profession. Such programs should usually conform to community requirements and to good public policy.

Bureau of Health and Public Instruction

As a result of the enlargement and alteration of the Association's building, more commodious and better appointed quarters have been provided for the Bureau of Health and Public Instruction. With improved facilities and enlargement of the official staff, it has been made possible for the Bureau to handle a much larger amount of work and to do its work more efficiently.

CORRESPONDENCE

More than 20,000 written communications were received during the year. The number of letters received as a result of the radio broadcasting program of the Association was more than six times the number of similar communications received in the previous year. There also was a large increase in the number of letters received from laymen asking for specific information about matters pertaining to health and to the prevention of disease. Such growth in the work of the Bureau involves a consideration of what may be expected in the future. The better the service rendered, the greater the demands made on the Bureau for providing information. It is confidently expected that the continuation of the radio broadcasting program will inevitably produce a constantly increasing number of inquiries from the lay public.

RADIO PROGRAM

The weekly dramatized radio broadcasting program, initiated in October 1935, was continued without interruption until June 1936. In October 1936 the weekly programs were resumed and have been given each week with only one interruption, when the broadcasting period was relinquished in favor of a broadcast by the President of the United States. The total number of dramatized programs broadcast up to the time of the preparation of this report is forty-four over the National Broadcasting Company network and one over the Columbia Broadcasting System. Additional broadcasts over the National Broadcasting Company facilities and over the Columbia Broadcasting System were made as a part of a special program at the time of the annual session of the Association held in Kansas City in May 1936.

In view of the special nature of the dramatized presentations and the large amount of favorable attention which the broadcasting program attracted in its first season, the closest possible attention has been given to the difficult problem of maintaining the quality of this program. Officials of the National Broadcasting Company have indicated that there is no falling off in the attraction value of the dramatized presentations. Important publications have commented most favorably, and the president of the Radio Corporation of America has included the Association's dramatized radio broadcast as one of the six outstanding educational programs on the networks of the National Broadcasting Company.

The Bureau has continued the maintenance of the radio library, intended to be used for aiding component and constituent associations that may desire to conduct broadcasting programs. During the year, ninety-four new radio talks were added to the library so that the total number of titles is now 873. The use of this library by state and county medical societies apparently is diminishing, and it is possible that this is to be explained by the evidently increasing popularity of the dramatized presentations of the American Medical Association.

The National Broadcasting Company has contributed in great measure to the success of the educational radio program, and its official representatives have at all times been generous in extending their individual cooperation.

COOPERATION WITH STATE AND COUNTY MEDICAL SOCIETIES
AND OTHER ORGANIZATIONS

The Bureau has continued its cooperation with state and county medical societies and with other organizations by attempting to act as a clearing house for information concerning health and to further cordial relations between the medical profession and organizations of various kinds that have interested themselves in public health matters, including, especially, official health departments. For these purposes the Director of the Bureau has attended conferences with the Joint Committee on Health Problems in Education, the organization of state and territorial health officers with the Children's Bureau of the U. S. Department of Labor, groups of officers of medical societies, the American Public Health Association, the First National Conference on Educational Broadcasting, the National Conference on College Hygiene, the Conference on Venereal Disease Control Work, the General Federation of Women's Clubs Advisory Committee, and other groups.

It may be said, in general, that the attitude of organizations with which cooperative contact has been made has been very

satisfactory. The attitude of officials of the federal government has been friendly and cooperative. It would appear that the maintenance of such contacts already established and the furtherance of additional contacts will be highly desirable and necessary for promoting the interests of the organized medical profession and providing such aid as the profession can give to worthy organizations that are interested in the promotion of the public health. Policies adopted at gatherings of national scope frequently may be expected to percolate very slowly and, perhaps, unsatisfactorily, to the ultimate point where a definite program may be applied in the local community. It will require the exercise of patience and intelligent effort on the part of the medical profession to keep these nationwide programs on a satisfactory plane of sane and sensible operation and to provide the helpful guidance that no group other than the medical profession can offer.

One of the most important conferences pertaining to public health was the Conference on Venereal Disease Control Work called by the Surgeon General of the United States Public Health Service, the details of which were summarized in an editorial that appeared in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Jan. 9, 1937. This conference was well organized and well attended. In its deliberations, full recognition was given to the importance of the general practitioner of medicine in any plan designed to effect better control of venereal diseases.

HYGEIA CLIPPING LOAN COLLECTIONS

The loan service of HYGEIA clippings, begun experimentally in 1932, was developed to the degree originally planned and intended for the first time in 1936. Collections of clippings are, on request, lent to physicians without charge. Physicians who avail themselves of the use of this material are expected to return the collections within ten days and to pay return postage. Physicians in thirty-eight states have availed themselves of this service.

PROTECTION FOR MEDICAL RESEARCH

This bureau has attempted to cooperate with the Committee for the Protection of Medical Research and, in an effort to be helpful in this direction, has distributed among the students of medical schools more than 5,000 copies of the pamphlet entitled "Animals in Research."

COOPERATION WITH LAY ORGANIZATIONS

The Director of the Bureau of Health and Public Instruction has served as a member of official committees of a number of important lay organizations of national scope.

The National Congress of Parents and Teachers has continued its efforts to have its Summer Round-Up conducted on a basis satisfactory to the medical profession and has placed special emphasis on the desirability of having examinations of children made by the family physician rather than through assembled group clinics. More emphasis has been placed on proper compensation for physicians' services in connection with the Summer Round-Up examinations. Through the Bureau, the American Medical Association has continued to provide a certain number of the examination forms for use in the Summer Round-Up.

The General Federation of Women's Clubs, through its Department of Health and Welfare, has continued its program and, during 1936, promoted a program of education of its own members with respect to maternal hygiene and other important subjects. The federation, like the National Congress of Parents and Teachers, shows a very definite desire to cooperate as fully as possible with the medical profession.

The National Committee for Boys' and Girls' Club Work is carrying on in individual communities programs of constructive character in health education and health promotion.

The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association has continued its activities, as indicated in previous reports and in special reports submitted to the Board of Trustees of the Association.

It seems perfectly evident that in the future the importance of preventive medicine will be stressed more than ever before, and it is highly desirable that the closest possible cooperation

should exist between the organized medical profession, official departments of health and special organizations whose purpose is to promote the betterment of the general health.

FIELD WORK

During the year the Director and Assistant Director of the Bureau appeared as participants in the programs of medical societies in various parts of the United States and also appeared before a number of meetings arranged by lay organizations. The total number of addresses delivered was ninety-two. Numerous invitations to appear at meetings arranged by medical societies or under the auspices of lay groups had to be declined because of the pressure of other official duties.

OTHER ACTIVITIES

The Bureau has continued its cooperation with other departments of the Association and has prepared a large amount of material for publication in *THE JOURNAL* and in other publications, including *HYGELA*. In cooperation with the Bureau of Exhibits, exhibit material was prepared for the Association's exhibits at the California-Pacific International Exposition, the Texas Centennial Exposition, the meeting of the American Public Health Association and the annual session of the American Medical Association at Kansas City.

An important part of the work of the Bureau of Health and Public Instruction has to do with the printing and distribution of pamphlets of an educational nature. Seventeen new pamphlets were added to the list of Bureau publications in 1936, while two of the older pamphlets were revised and five discontinued.

Summary

Better and more commodious quarters have been provided and the activities of the Bureau of Health and Public Instruction have been expanded.

The dramatized radio broadcasting programs initiated in 1935 have been continued and have attracted widespread interest. Ninety-four new "radio talks" have been added to the radio library maintained for the use of state and county societies.

The Bureau has attempted to cooperate as fully as possible with component and constituent societies and with other worthy organizations. The Director has served as a member of advisory committees of several important lay organizations of national scope.

The Director and his assistant participated in the programs at ninety-two meetings of professional and lay groups during the year.

There was a material increase in correspondence in 1936, many inquiries having come from laymen.

Bureau of Investigation

The Bureau of Investigation continues to receive many requests for information pertaining to the subjects with which the Bureau is concerned. During 1936 approximately 10,000 direct inquiries were received and answered, these inquiries being about equally divided between laymen and physicians. In previous years each of such inquiries generally has contained a single question, but lately many of them ask for information concerning several different matters. Careful attention is given to each item and, in some instances, it is necessary to give much time and effort to secure authentic information on which replies can be properly based.

In addition to inquiries and requests received from individuals, a great many come from newspapers, magazines and radio broadcasting stations, most of them pertaining to advertising offered for publication or for broadcasting. Teachers and students are constantly utilizing the services of the Bureau of Investigation, and there is considerable demand from these sources for pamphlets, posters and educational material.

During the year the Bureau has attempted to be of assistance in a number of instances to the Federal Trade Commission, the Food and Drug Administration, the Post Office Department and the Federal Bureau of Investigation as well as to Better Business Bureaus and law enforcement agencies in various cities.

An entirely new and revised edition of *Nostrums and Quackery and Pseudo-Medicine* was published in December 1936, the revision having been made by Dr. Arthur J. Cramp,

formerly Director of this Bureau. Thirteen articles prepared by the Director of the Bureau appeared in *THE JOURNAL* during the year covered by this report.

The demand made on the Bureau's lantern slide loan service was about equal to that of previous years. This service is utilized most largely by physicians, health officers and educators in connection with lectures dealing with "patent" medicines and medical frauds.

The Director of the Bureau delivered twenty-two addresses during the year, nearly all of them having been presented to lay audiences.

Summary

Approximately 10,000 direct inquiries from laymen and physicians were received and answered by the Bureau in the past year. The Bureau has attempted to be of assistance to various departments of the federal government and to Better Business Bureaus and official agencies of various cities. There has been the usual demand for the publications of the Bureau.

A new edition of *Nostrums and Quackery and Pseudo-Medicine*, completely revised, came from the press in December 1936.

The Director of the Bureau appeared before twenty-two audiences in various states during the year and prepared thirteen articles for publication in *The Journal*.

The material available through the lantern slide loan service of the Bureau continues to be utilized by physicians, health officers and educators.

Bureau of Exhibits

The Bureau of Exhibits is concerned with the administration of the work of the Committee on Scientific Exhibit, which is in charge of the scientific exhibits at annual sessions of the Association, with the preparation, distribution and in some instances the installation of exhibit material shown at meetings of scientific organizations, with the preparation, installation and supervision of exhibit material displayed at conventions and expositions, and with the preparation and distribution of educational exhibits lent for display under the auspices of important semiscientific and lay organizations.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Kansas City session, while smaller than that at the annual session in the preceding year, entirely filled available space. Because of the lack of room it became necessary to omit some excellent individual exhibits. Considerably more than 200 applications for space in the Scientific Exhibit at Kansas City were received, and 174 of them were accepted. Two special exhibits, made possible through appropriations by the Board of Trustees, were also shown at Kansas City.

The Council on Scientific Assembly and the officers of the sections cooperated closely with the Committee on Scientific Exhibit, so that subjects treated in thirty-eight papers read before the sections were dealt with in the exhibits. Each section of the Scientific Assembly appointed a committee to assist the Committee on Scientific Exhibit in obtaining desirable material, and the services of these section representatives were of great value and were gratefully appreciated.

The exhibits at the Kansas City session covered almost the entire field of medicine and some of the allied sciences and attracted genuine interest on the part of physicians in attendance, since the exhibit hall was crowded with visitors throughout the entire session.

The special exhibit on diabetes was made possible through the active assistance of the following committee: Drs. E. P. Joslin, Charles H. Best, Louis I. Dublin, Ralph H. Major, Howard F. Root, Bernard Smith and Russell M. Wilder. This exhibit was splendidly demonstrated and, in addition, thirty-four short talks on the subject of diabetes were made by splendidly qualified physicians in a room appointed for the purpose, where motion pictures on diabetes also were shown at various intervals during the session.

The special exhibit on fractures was prepared under the direction of a committee consisting of Drs. Kellogg Speed, Frank D. Dickson and Walter Estell Lee. This committee had

the assistance of an advisory committee composed of prominent surgeons from various parts of the United States. Fifty-two physicians assisted in the demonstration of the exhibit. Efficient service, through the courtesy of the Surgeon General of the United States Army, Colonel E. M. Blanchard and men from the Station Hospital at Kansas City, was rendered in connection with the fracture exhibit. Without their much appreciated services, the value of this exhibit would have been greatly lessened. The management of St. Luke's Hospital in Kansas City provided nurses and some supplies for the exhibit on fractures, and sincere appreciation for the fine work rendered by the nurses is here acknowledged.

The Committee on Awards, composed of Drs. Ludvig Hektoen, A. H. Aaron, Walter Freeman, Thomas Parran Jr. and W. W. Wasson, gave devoted service in discharging the important task assigned to it, which was made more difficult by reason of the wide scope of the exhibits and the excellence of the material that required their consideration. The members of this committee were on duty continuously for three days. It is evident that their judgment in making awards was beyond criticism, since no word of complaint has been heard.

ASSOCIATION EXHIBITS

Exhibit material depicting the work of the various councils, bureaus and departments of the American Medical Association has been prepared by the Bureau of Exhibits with the cooperation of administrative officers, and this material has been used widely. On more than 100 occasions, exhibits were shown during the year 1936 at the meetings of state and county medical societies and of approved scientific organizations, at public expositions, fairs and conventions. No material has been sent for exhibit purposes in any community except with the approval of the constituent state medical association or component county medical society concerned. At times as many as ten separate exhibits were being shown in widely separated places at the same time. Material prepared by the Bureau was exhibited in twenty-eight states. On several occasions, exhibits have been lent to state medical associations for a period of three weeks to be routed throughout the state on schedules arranged by the officers of the state associations.

Special exhibits were prepared and shown at the request and with the cooperation of the State Medical Association of Texas and the California Medical Association for the Texas Centennial Exposition and the California-Pacific International Exposition. The material shown in these exhibits was seen by great numbers of those in attendance at the expositions.

CENTRAL SCIENTIFIC EXHIBIT

The Central Scientific Exhibit, formerly installed in the Association's own building, was turned over to the Rosenwald Museum of Science and Industry in 1934. This exhibit has not yet been permanently installed because of the unfinished condition of the museum. It is understood that the museum building is now being completed. From time to time the Bureau of Exhibits has been permitted to utilize material which eventually will be permanently installed in the Museum of Science and Industry.

Summary

The Scientific Exhibit at the Kansas City session, while smaller than the exhibit of the preceding year, was of high quality and filled all available space. The Council on Scientific Assembly and the officers of the scientific sections cooperated closely with the Committee on Scientific Exhibit and with the Bureau.

The special exhibits on diabetes and fractures were of high quality and were splendidly demonstrated.

Exhibits were installed at the California-Pacific International Exposition and at the Texas Centennial Exposition.

National Department of Health

At various times within the last twenty-five years, proposals have been advanced that a national department of health with a member of the President's cabinet at its head should be established by the federal government. The American Medical Association, through its House of Delegates, has on more than one occasion expressed approval of the idea that a national

department of health under qualified direction should be established on the ground that the medical and public health activities of the federal government cover such wide scope and are of such great importance to the general welfare that they might well be administered under a central agency, with qualified administrative officers, on the same footing as other major departments of the federal government.

It is only fair to say in this connection that there never has been complete unanimity of opinion among the members of the medical profession in the United States with respect to such proposals, largely because there has been a fear in the minds of some physicians that at some time a national department of health, if established by the federal government, might come to be under the direction or control of administrators not well qualified to direct the medical and public health affairs of the government.

Within recent years there has been discussion at various times of proposals to the effect that a department of social welfare, charged with the administration of governmental functions pertaining to education, to medicine and public health and to social service, should be established. Such proposals, having come to the attention of the Board of Trustees, were given careful study and, at a special meeting Jan. 8, 1937, the following statement pertaining to reorganization of governmental activities was adopted as representing the considered opinion of the Board of Trustees:

"Recognizing that committees of the Senate and of the House of Representatives of the United States government and a special committee appointed by the President are at this time concerning themselves with the reorganization of government activities with a view to greater efficiency and economy, and recognizing also that the President, in his opening address to Congress, indicated that he would shortly present to the Congress recommendations for such reorganization of governmental activities in the executive branches, and recognizing moreover the great desirability that all activities of the federal government having to do with the promotion of health and the prevention of disease might with advantage be consolidated in one department and under one head, the Board of Trustees of the American Medical Association would recommend that such health activities as now exist be so consolidated in a single department which would not, however, be subservient to any charitable, conservatory or other governmental interest. It has been repeatedly said that public health work is the first problem of the state. It is the opinion of the Board of Trustees that health activities of the government, except those concerned with the military establishments, should not be subservient to any other departmental interests. This reorganization and consolidation of medical departments need not, under present circumstances, involve any expansion or extension of governmental health activities but should serve actually to consolidate and thus to eliminate such duplications as exist. It is also the view of the Board of Trustees that the supervision and direction of such medical or health department should be in the hands of a competently trained physician, experienced in executive administration."

Copies of this statement as printed in *THE JOURNAL* were transmitted to the President of the United States and to others in official position in Washington, and the attention of the constituent state medical associations was especially called to the action of the Board. Soon afterward the President, in accordance with a statement made in his opening address to Congress, submitted a special message to Congress on the reorganization of governmental departments and, in this message, recommended the creation of a department of social welfare.

Extension of Medical Service to the Indigent

At the special meeting of the Board of Trustees held Jan. 8, 1937, the following statement pertaining to medical service to the indigent was adopted and later appeared in *THE JOURNAL*:

"In the past, the medical profession has always been willing to give of its utmost for the care of those unable to pay. The available evidence indicates that today throughout the United States the indigent are being given a high quality of medical care and medical service. Nevertheless, the advances of medical science have created situations in which a group of the

population neither wholly indigent nor competent financially find themselves under some circumstances unable to meet the costs of unusual medical procedures. The Board of Trustees of the American Medical Association points out the willingness of the medical profession to do its utmost today, as in the past, to provide adequate medical service for all those unable to pay either in whole or in part. Members of the medical profession, locally and in the various states, are ready and willing to consider with other agencies ways and means of meeting the problems of providing medical service and diagnostic laboratory facilities for all requiring such service and not able to meet the full cost thereof. These are problems for local and state consideration primarily rather than problems of federal responsibility. The willingness of the medical profession to adjust its services so as to provide adequate medical care for all the people does not constitute in any sense of the word an endorsement of health insurance, either voluntary or compulsory, as a means of meeting the situation."

Occupational Diseases and Industrial Medicine

At the Kansas City session a resolution introduced by Dr. A. R. McComas, Missouri, pertaining to the control of occupational diseases was referred to the Reference Committee on Hygiene and Public Health. This committee, after conferences with the sponsor of the resolution and others interested, submitted the following substitute resolutions, which were approved by the House of Delegates:

WHEREAS, In recent years there has developed an increase in recognition of the seriousness of diseases arising from conditions to which workers are exposed from certain occupations; and

WHEREAS, The diagnosis of such diseases is possible only by physicians, and the correction of such conditions as would tend to eliminate the hazards can best be carried out under the guidance and administration of physicians, particularly physicians trained and experienced in industrial hygiene or public health; therefore be it

Resolved, That it be deemed essential that any active efforts by governmental agencies to study and to take measures tending to eliminate occupational diseases should be carried out under the supervision of the city, state or federal departments of health in this country and that this Association do all within its power to assist in this endeavor; and be it further

Resolved, That the Board of Trustees of this Association continue and enlarge its study of industrial hygiene, occupational diseases, and particularly silicosis, to the end that uniform legislation be put into effect in all the states to control these conditions.

The importance of matters to which these resolutions pertain had been previously recognized by the Board of Trustees, and the Bureau of Legal Medicine and Legislation and other official agencies of the Association had given close attention to various developments and organized movements in the general field of industrial medicine. The Section on Dermatology and Syphilology also had interested itself rather extensively in the study of industrial dermatoses and had adopted a report of a special committee of the section asking for the cooperation of the Association in the establishment of "a central clearing house" for the accumulation and recording of information on industrial dermatoses.

These matters were further considered by the Board of Trustees at official meetings held during the year 1936, and March 12, 1937, a conference was held, participated in by the members of the Executive Committee of the Board of Trustees and a group of physicians who were known to have given careful study to the various problems involved in the general field of industrial hygiene. Members of the Association's administrative personnel also were present. The group invited to attend this conference included medical representatives of the United States Public Health Service, of industrial organizations and of insurance companies and physicians engaged in private practice. After a most illuminating discussion, which lasted through the greater part of a whole day and was participated in by all who were present, it was apparent that there was unanimous opinion to the effect that the American Medical Association should establish a council to deal with matters pertaining to the control and prevention of occupational disease and to the administration of medical services established by industrial organizations.

The recommendation of the conference was to the effect that a council to be known as the Council on Industrial Health should be established and maintained by the American Medical Association.

To include in this report a complete statement setting forth the reasons that might be advanced in support of the proposal to establish a Council on Industrial Health would require an undue amount of space, but a complete account of the proceedings of the conference referred to will be placed at the disposal of the House of Delegates or of the Reference Committee to which this matter is referred for consideration.

The Board of Trustees desires to express its appreciation for the suggestions and advice of the group of physicians who attended the conference with the Executive Committee and to acknowledge gratitude to them for their generous and valuable contribution toward the proper consideration of the proposals for the creation of a Council on Industrial Health.

Motion Picture on Syphilis

In view of the widespread interest aroused through the activities of the United States Public Health Service in promoting plans for better control of venereal disease, the Board of Trustees has entered into cooperative arrangements with the United States Public Health Service in the production of a motion picture on syphilis. Plans have been made for the showing of this picture at the Atlantic City session. Copies of the film will be made available for the use of constituent and component medical societies, and it is earnestly hoped that the picture will have great educational value.

Appointment of Committees

In accordance with the provisions of resolutions submitted to the House of Delegates at the Kansas City session, the following committees were appointed by the Board of Trustees, the President or the Speaker of the House of Delegates, as indicated:

Committee to Study Air Conditioning, appointed by the Board of Trustees: Dr. Carey P. McCord, chairman, Detroit; Dr. Emery R. Hayhurst, Columbus, Ohio; Dr. William F. Petersen, Chicago; Dr. H. B. Williams, New York; Prof. C. P. Yaglou, Boston.

Committee on Asphyxia, appointed by the Board of Trustees: Dr. Paluel J. Flagg, Chairman, New York; Dr. John S. Lundy, Rochester, Minn.; Dr. Thomas J. Vischer, Philadelphia.

Committee on Medicolegal Blood Grouping Tests, appointed by the Board of Trustees: Dr. Ludvig Hektoen, chairman, Chicago; Dr. Karl Landsteiner, New York; Dr. Alexander S. Wiener, Brooklyn.

Committee to Study Problems of Motor Vehicle Accidents, appointed by the President: Dr. Herman A. Heise, chairman, Milwaukee; Dr. Burt R. Shurly, Detroit; Dr. Thomas A. McGoldrick, Brooklyn; Dr. C. W. Roberts, Atlanta, Ga.; Dr. Cary T. Grayson, Washington, D. C.

Committee to Propose Amendment to By-Laws Providing for Fitting Recognition to Fellows Rendering Distinguished Service in Science of Medicine, appointed by the Speaker of the House of Delegates: Dr. H. H. Shoulders, chairman, Nashville, Tenn.; Dr. John W. Ames, Denver; Dr. J. D. Brook, Grand Rapids, Mich.; Dr. John F. Hassig, Kansas City, Kan.; Dr. Grant C. Madill, Ogdensburg, N. Y.

The Board of Trustees also appointed during the year a Committee to Determine the Value of X-Ray Film with Paper Base as a Substitute for Film with Gelatin Base, the members of which are as follows: Dr. Hollis E. Potter, chairman, Chicago; Dr. Edward H. Skinner, Kansas City, Mo.; Dr. H. Kennon Dunham, Cincinnati; Dr. J. A. Myers, Minneapolis; Dr. Homer L. Sampson, Trudeau, New York.

Reports of these committees which are not contained in this Report of the Board of Trustees are to be presented to the House of Delegates at the Atlantic City session.

Respectfully submitted.

ROCK SLEYSER, Chairman.
JAMES R. BLOSS.
AUSTIN A. HAYDEN, Secretary.
ARTHUR W. BOOTH.
ALLEN H. BUNCE.
THOMAS S. CULLEN.
RALPH A. FENTON.
ROGER I. LEE.
CHARLES B. WRIGHT.

ADDENDA TO REPORT OF BOARD
OF TRUSTEES

Report of Committee to Study Air Conditioning

Following a resolution, introduced and favorably passed on in the House of Delegates during the Kansas City session in 1936, the Board of Trustees, during a September meeting, created a Committee to Study Air Conditioning. The following persons were appointed on this committee: Dr. Emery R. Hayhurst, Columbus, Ohio; Dr. William F. Petersen, Chicago; Dr. H. B. Williams, New York; Mr. C. P. Yaglou, Boston, and Dr. Carey P. McCord, Detroit. In November 1936 the members of the committee were called together for organization purposes. With all committeemen in attendance, the decision was made to undertake as a first objective the compilation and publication of a series of authoritative articles related to various aspects of air conditioning. The topics to be covered in early publications include "The Physiologic Changes in Human Beings Related to Atmospheric Conditions," "The Pathology of Disease States Attributable to Unsuitable Atmospheric Conditions," "The Field of Application for Artificial Air Conditioning," "The Requirements of Air Conditioning for Hospitals" and "The Clinical Manifestations of Abnormal States Attributable to Unsuitable Air Conditions." For collaboration on the last named topic, a subcommittee was created, consisting of Dr. Henry Hurd, New York; Dr. Howard Hartman, Rochester, Minn.; Dr. Thomas Crowder, Chicago, and Dr. Lee Bristol, New York.

By the time of the Atlantic City session, 1937, three of the committee's reports will have been published or will be ready for publication. These reports respectively will deal with the "Physiologic Requirements of the Human Body as to Air Conditioning," Part I "During Summer Months" and Part II "During Winter Months" and "The Requirements of Hospitals as to Air Conditioning."

For the necessary expenses of this committee, an appropriation of \$2,500 was made by the Board of Trustees. Of this sum, \$700 has been set aside for the compilation of a complete bibliography on air conditioning. This preparation of bibliography material has been undertaken jointly by Professor Yaglou and Dr. Hayhurst, members of the committee, together with Dr. Teleky of Europe, who is bringing together the most important foreign material related to air conditioning.

The items of work now under way will be completed about Dec. 31, 1937.

CAREY P. MCCORD, Chairman.
H. B. WILLIAMS.
E. R. HAYHURST.
W. F. PETERSEN.
C. P. YAGLOU.

Report of the Committee on Asphyxia

THE PROBLEM

Asphyxia as a terminal complication precedes numerous deaths and widespread morbidity from a variety of causes. The question What can be done through the prevention and treatment of asphyxia? has been raised and your committee has been called on to make a short report without the benefit of an exhaustive study of the question.

It is conceded that the problem had best be attacked without haste. In time, the work may be so organized as to permit a reasonable expectancy of success. Of necessity, omissions of more or less important aspects of the problem will occur. We propose, however, to consider these as they appear, limiting our attention at this time to those groups in which the prevention of asphyxia or its treatment offers a problem of sufficient importance to engage the attention and enlist the action of the Trustees of the American Medical Association. The fields which, we believe, need immediate attention are to be noted as follows:

1. Asphyxia neonatorum.
2. Asphyxia from gases, used industrially.
 - (a) Carbon monoxide from illuminating gas and from engine exhaust.
 - (b) Refrigerants such as ammonia, carbon dioxide and dry ice.
 - (c) Fumes in the manufacture of chemicals.
 - (d) Gases associated with the oil industry.
 - (e) Gases in the mining industry.
 - (f) Fumigation for disease; the destruction of rodents on board ship and elsewhere.

3. Asphyxia from gases, in warfare.
4. Asphyxia from drugs, hypnotics, narcotics and sedatives, including acute alcoholism.
5. Asphyxia from disease, such as acute pulmonary conditions, asthma and cardiac decompensation.
6. Asphyxia from developmental and mechanical abnormalities, such as neonatal atelectasis and collapse of the lung.
7. Asphyxia from anesthesia due to overdosage, idiosyncrasy or a failure to meet mechanical obstruction, occurring in relaxation.
8. Asphyxia from drowning (submersion).
9. Asphyxia from flying at high altitudes.
10. Asphyxia from fire fighting (smoke, chemical poisoning).
11. Asphyxia from obstruction by foreign bodies.
 - (a) Material caught in the esophagus or inhaled.
 - (b) Tumors or infections within or without the airway.
12. Asphyxia from electrocution.
13. Asphyxia from strangulation.
14. Asphyxia from allergy.
15. Asphyxia from terminal poliomyelitis.

TREATMENT IS SIMILAR, IRRESPECTIVE OF THE CAUSE

It will immediately be asked Why are so many apparently unrelated entities considered under the head of asphyxia? The reason for so considering the many and various causes of asphyxiation is that, once the predisposing or immediate causes of asphyxiation are removed, the treatment, regardless of the etiology, is always the same. For example, once the electrocuted person is detached from the current causing the accident, the submerged patient is lifted out of the water or the foreign body is removed, the basic problem in each case is reduced to the introduction of oxygen into the respiratory tract, the support of the centers governing respiration, and the stimulation of the circulation.

The brevity of this report precludes the consideration of detailed specific information for the conditions inducing asphyxiation.

METHODS BY WHICH THE PROBLEM OF ASPHYXIATION
MAY BE ATTACKED

Your committee believes that the attack on the problem of asphyxia lies in:

Publicity, by which the attention of the medical profession and the public may be directed to the frequency of death due to asphyxiation.

Organization, to coordinate available information as well as agencies and groups whose normal activity bring them into frequent contact with asphyxial emergencies.

Action, developed as the result of publicity and organization. To stimulate research and to develop a personnel, both lay and medical, capable of carrying out treatment appropriate for the specific case.

The problem of asphyxiation is one that extends outside the immediate confines of the practice of medicine. It impinges directly on industry and the utilities and forms a vital problem in the defense of the nation against gas attacks by a foreign power.

While much valuable work has been done through statistical and other studies conducted by industrial organizations, attacking the problem of carbon monoxide and other specific causes of gas poisoning, and while measures to reduce asphyxiation from drowning have been intensively carried out, notably by the state of Rhode Island, and while first aid measures made available through many police and fire departments leaves little to be desired, your committee is nevertheless impressed by the sporadic and limited nature of such efforts, the lack of publicity attending successful organization, and the entirely unwarranted publicity frequently accompanying unscientific efforts to treat asphyxiation.

Your committee is furthermore impressed by the need of proper organization and supervision of lay groups by a trained and experienced medical personnel. Coordination between the physician and the lay group is often entirely lacking and might well be encouraged. There is not so much a lack of information on the subject of asphyxia as there is a lack of a general knowledge of available technic and equipment. Furthermore, while the specific treatment of any of the stated causes of asphyxiation is well known to those who have done special work on the problem, such treatment developed as a medical routine is by no means the common property of practicing physicians.

The recognition of the problem of asphyxia, implying as it does the loss of at least 50,000 lives a year, brings with it the challenge to reduce these deaths by a carefully worked out program to be carried out over a long period.

PROPOSED COMMITTEE PROGRAM

General.—Your committee believes that it may be of immediate service to the American Medical Association by acting in an advisory and coordinating capacity.

This assistance and coordination may take the form of a continued program, including a method of attack by public education, research, and the postgraduate instruction of physicians.

Arrangements may be made for the preparation of a series of articles in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*

Questions relative to resuscitation apparatus and technic referred to it from the Council on Physical Therapy may well come under its purview.

Your committee suggests the desirability of taking over the work and carrying on the program initiated and maintained for the last four years by the Society for the Prevention of Asphyxial Death. Informative material accumulated by this organization might be filed by the committee for the use of the Association, and contacts with organizations and groups interested in the prevention of asphyxial death may be preserved and developed.

Your committee believes that it may be helpful and awaits instruction and power to act as a coordinating agency in the assembly of information from and the dissemination of information through the various committees and bureaus of the American Medical Association.

Realizing the magnitude of the task presented by the problem of asphyxiation, its presentation and control, your committee feels it necessary to reaffirm its conviction that progress can be made only by a well planned attack over a period of time.

Specific and Immediate Steps.—Of fundamental importance in the preparation of this attack is the assembly of exact information to be used in the listing of asphyxial deaths. There must be established, first of all, a clear cut and generally accepted list of causes of asphyxiation; secondly, these causes must appear in national death returns, where they may be segregated and studied. Such returns may be reported each year and reduced mortality, due to preventative measures, noted. Your committee suggests that such an annual report of vital statistics relative to asphyxiation appear annually in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* at a stated date.

Following the accumulation and analysis of asphyxia statistics, intensive efforts may be made to reduce asphyxiation in the various groups in which it is most prevalent. For example, an early and a concentrated effort might well be made to reduce asphyxia in the new-born, since this type of asphyxiation constitutes more than 60 per cent of the total asphyxia mortality. Synchronously or at a later period, asphyxiation from gases used industrially, from gases in warfare, from submersion, from foreign body obstruction, from anesthesia, from drugs and from disease may each receive attention in the order of importance.

In conclusion, your committee requests the necessary financial assistance to carry out the recommendations reported.

Respectfully submitted.

JOHN S. LUNDY.

THOMAS J. VISCHER.

PALUEL J. FLAGG, Chairman.

Report of the Committee on Scientific Research
for 1936

During the year eighty-two applications received consideration and forty-four awards were made. As heretofore, the new grants support research in various medical fields. Almost without exception, the money has been turned over to the financial officer of the institution in which the grantee works, the understanding being that it would be subject to requisitions by the grantee and that an accurate account of the expenses would be kept. The final or practically final results of work under twenty-six grants have been published or are in the course of publication. The results of the work under thirteen grants prior to 1936 are being prepared for publication. Under thirty-four grants prior to 1936 active work is still in progress; in several cases reports on results have been published. In the case of four grants the files have been closed without any

publication of results. Refunds amounting to \$1,515.20 have been made during the year of unexpended balances from grants.

The committee would recommend that the same appropriation be made for 1937 as for 1936; namely, \$12,550 for grants

in aid of medical research and \$1,200 for committee expenses. The financial statement for 1936 is presented; also brief accounts of grants pending at the end of 1935 and a list of grants made in 1936.

Respectfully submitted.

COMMITTEE ON SCIENTIFIC RESEARCH OF
THE AMERICAN MEDICAL ASSOCIATION
LUDVIG HEKTOEN, Chicago, Chairman.
Term expires, 1941.
C. C. BASS, New Orleans.
Term expires, 1937.
JOHN J. MORTON, Rochester, N. Y.
Term expires, 1938.
N. W. JONES, Portland, Ore.
Term expires, 1939.
MARTIN H. FISCHER, Cincinnati.
Term expires, 1940.

GRANTS OF COMMITTEE ON SCIENTIFIC RESEARCH

NEW GRANTS—1936

- Grant 393: Lloyd H. Ziegler and Arthur Knudson, Albany Medical College, \$165, effect of rickets on activity of rats.
- Grant 394: Charles Huggins, University of Chicago, \$300, bone marrow.
- Grant 395: Israel S. Kleiner, New York Homeopathic Medical College, \$350, formation of cevitamic (ascorbic) acid.
- Grant 396: Valy Menkin, Harvard Medical School, \$600, iron metabolism and effect of ferric chloride on tuberculosis.
- Grant 397: R. F. Hanzal, Western Reserve University, \$150, source of endogenous uric acid and the effects of methylated xanthines on its secretion.
- Grant 398: George A. Emerson, West Virginia University, Morgantown, \$175, metabolic products of sympathomimetic amines.
- Grant 399: Felix Saunders, University of Chicago, \$250, essential growth factor for bacteria.
- Grant 400: John Field, Stanford University, \$200, effect of dinitrophenol on the lens.
- Grant 401: W. T. Dawson, University of Texas, Galveston, \$200, toxicity of cardiac glucosides.
- Grant 402: C. H. Thienes and L. T. Samuels, University of Southern California, \$500, carbohydrate metabolism as influenced by the hypophysis.
- Grant 403: Samuel Soskin, Michael Reese Hospital, Chicago, \$750, laboratory tests for endocrine dysfunctions.
- Grant 404: Peter Heinbecker, Washington University, St. Louis, \$750, mechanism of altered sensitivity of smooth musculature to epinephrine.
- Grant 405: M. M. Wintrobe, Johns Hopkins University, \$200, vertebrate red corpuscles.
- Grant 406: Helen B. Coombs, New York Homeopathic Medical College, \$200, action of acetylcholine on the central nervous system.
- Grant 407: Ralph I. Dorfman, Louisiana State University, \$250, estrogenic substance in human urine and other estrogenic compounds.
- Grant 408: Gustav J. Martin, Trudeau Sanatorium, Trudeau, N. Y., \$200, lipoids of tubercle bacilli.
- Grant 409: Lester R. Dragstedt and G. M. Dack, University of Chicago, \$600, relation of *B. necrophorum* to chronic ulcerative colitis in man.
- Grant 410: H. E. Eggers, University of Nebraska, \$200, effect of tetra-methyl-arsonium gluconate on human cancer.
- Grant 411: Fae D. Wood, University of California at Los Angeles, \$125, distribution of *Trypanosoma cruzi* in southwestern United States.
- Grant 412: Robert H. Gault and A. C. Ivy, American Institute for Deaf-Blind, Evanston, Evanston, Ill., \$400, stimulation of vibrotactile organs by mechanical vibrations.
- Grant 413: Philip Levine, Newark Beth Israel Hospital, Newark, N. J., \$350, bacteriophage action in the dysentery group.
- Grant 414: John R. Murlin, University of Rochester School of Medicine and Dentistry, \$600, testis hormone.
- Grant 415: Gordon H. Scott, Washington University, St. Louis, \$300, lead and aluminum in cerebrospinal fluid.
- Grant 416: Jean Broadhurst, Teachers College, Columbia University, \$200, inclusion bodies in the female genital area.
- Grant 417: Isaac Schour, University of Illinois College of Dentistry, \$400, parathyroids in calcium metabolism.
- Grant 418: Frank W. Allen, University of California, \$200, nucleotide of the red corpuscles.
- Grant 419: Carl A. Dragstedt, Northwestern University Medical School, \$250, rôle of histamine and of adrenal cortex extract in anaphylaxis in the dog.
- Grant 420: Arthur Knudson, Albany Medical College, \$400, synthesis of cholesterol in the animal body.
- Grant 421: W. R. Tweedy, Loyola University, Chicago, \$150, action of parathyroid extract.
- Grant 422: T. Grier Miller, Hospital of University of Pennsylvania, \$300, chemical composition of human succus entericus and absorption of dextrose from small intestine.
- Grant 423: Alfred Gilman, Yale University, \$300, physiology of the antidiuretic hormone of the posterior pituitary.
- Grant 424: Charles P. Sheldon, Albany Medical College, \$200, respiration in pregnancy and labor.
- Grant 425: William J. Turner, State Tuberculosis Sanatorium, Crescon, Pa., \$50, uroporphyrins.
- Grant 426: H. P. Smith, State University of Iowa, \$500, blood clotting.
- Grant 427: Helen S. Mitchell, Massachusetts State College, \$300, nutritional cataract in rats.
- Grant 428: D. B. Phenemier, K. Grimson and H. Wilson, University of Chicago, \$400, effect of sympathectomy on blood pressure in dogs.
- Grant 429: Abraham White, Yale University, \$100, sulfur of proteins.
- Grant 430: S. W. Ranson, Northwestern University Medical School, \$315, fever producing agents.
- Grant 431: Benjamin Harrow, College of the City of New York, \$200, purification of the hyperglycemic factor in urine.
- Grant 432: Roe E. Remington, Medical College of the State of South Carolina, \$200, quantitative effect of iodine deficiency in the rat.

Grant 433: Frederick Lemere, Eastern State Hospital, Medical Lake, Wash., \$500, Berger brain rhythms in psychotic patients.

Grant 434: Wilbert H. McGaw, Western Reserve University, \$500, sound conduction in fractured bones.

Grant 435: Warren O. Nelson, Wayne University College of Medicine, Detroit, \$300, effect of synthetic androgenic substances.

Grant 436: Albert P. Krueger, University of California, \$300, nature of bacteriophage.

STATE OF WORK UNDER PREVIOUS GRANTS

1. COMPLETED DURING THE YEAR

Grant 218, 1931: Clayton, J. Lundy, Rush Medical College, Chicago, \$1,000 toward making animated motion pictures of the actions of the heart in health and in disease. See description of film showing normal heart action in *THE JOURNAL*, Dec. 23, 1933, page 2078. Honorable Mention, Scientific Exhibit, A. M. A., 1933. Lundy, C. J.: *The Heart Beat Mechanism in Health and Disease*, Heart Movie, six reels.

Grant 238, 1932: Harold E. Himwich, Yale University, \$1,000, the relation of the autonomic nervous system to metabolism and effect of alcohol on metabolism. Himwich, H. E., and associates: Effects of Alcohol on Metabolism, *Am. J. Physiol.* **101**: 57, 1932; Metabolism of Alcohol, *J. A. M. A.* **100**: 651, 1933. Barker, S. B.; Fazikas, J. F., and Himwich, H. E.: Metabolic Aspects of Thyroid-Adrenal Interrelationship, *Am. J. Physiol.* **115**: 415, 1936.

Grant 269, 1932: M. M. Wintrobe, Johns Hopkins Hospital, \$250, vertebrate red corpuscles. Wintrobe, M. M.: Variations in the Size and Hemoglobin Content of Erythrocytes in the Blood of Various Vertebrates, *Folia haemat.* **51**: 32, 1933. Wintrobe, M. M., and Shumacker, H. B., Jr.: Comparison of Hematopoiesis in the Fetus and During Recovery from Pernicious Anemia, *J. Clin. Investigation* **14**: 837, 1935. Wintrobe, M. M., and Shumacker, H. B., Jr.: Erythrocyte Studies in the Mammalian Fetus and New-Born, *Am. J. Anat.* **58**: 313, 1936. See grant 405, 1936.

Grant 276, 1933: Jessie L. King, Goucher College, Baltimore, \$75, effect of cortical extract on suprarenalectomized rats. See grant 391, 1935. King, Jessie L.: Effect of Massive Doses of Adrenal Cortical Hormone on the Albino Rat, submitted for publication in *Proc. Soc. Exper. Biol. & Med.*

Grant 314, 1934: Bernard Portis, Michael Reese Hospital, Chicago, \$300, immune reactions of Flexner-Jobling rat tumor. Portis, Bernard, and Roth, Harold: Effect of Immune Serum on Transplantable Flexner-Jobling Rat Carcinoma, *Arch. Path.* **22**: 722, 1936.

Grant 322, 1934: W. J. Nungester, Northwestern University Medical School, \$130, the effect of mucin on infection. See grant 352, 1935. Nungester, W. J., and Jourdonais, L. F.: Mucin as an Aid in the Experimental Production of Lobar Pneumonia, *J. Infect. Dis.* **59**: 258, 1936.

Grant 327, 1934: Timothy Leary, Office of Medical Examiner, Boston, \$800 for study of cholesterol atherosclerosis in rabbits (refund, \$48.63). Leary, Timothy: Atherosclerosis, the Important Form of Arteriosclerosis, a Metabolic Disease, *J. A. M. A.* **105**: 475, 1935. Leary, Timothy: Atherosclerosis: Special Consideration of Aortic Lesions, *Arch. Path.* **21**: 419, 1936. Leary, Timothy: Atherosclerosis: Etiology, *ibid.*, p. 459.

Grant 333, 1934: Arthur J. Geiger and Louis S. Goodman, Yale University, \$250, study of antianemic principle. (See also grant 340, 1934, and grant 382, 1935.) Goodman, L. S.; Geiger, A. J.; and Claiborn, L. N.: Antianemia Potency of Liver After Gastrectomy in Swine, *Proc. Soc. Exper. Biol. & Med.* **32**: 810, 1935. Goodman, L. S.; Geiger, A. J., and Klumpp, T. G.: Concerning the Specific Response of Guinea-Pig's Reticuloocytes to Substances Effective in Pernicious Anemia, *J. Clin. Investigation* **15**: 435, 1936.

Grant 341, 1934: Ludwig A. Emge, Stanford University School of Medicine, \$500, pregnancy and tumor growth. See grant 365, 1935. Emge, L. A., and Murphy, K. M.: The Relation of the Endocrine System to Tumor Growth, *Am. J. Obst. & Gynec.* **32**: 593, 1936.

Grant 342, 1934: S. S. Lichtman, Mount Sinai Hospital, New York, \$400, bile salt metabolism in liver disease. Lichtman, S. S.: The Blood Clearance and Renal Excretion of Bile Acids Following the Intravenous Injection of Cholic and Desoxycholic Acids, *Am. J. Physiol.* **117**: 665, 1936.

Grant 347, 1935: Edward S. West, University of Oregon Medical School, \$300, hydroxylated fatty acids in tissues. Hafner, P. G.; Swinney, R. H., and West, E. S.: Hydroxylated Acids of Fats: An Improved Method of Determination, *J. Biol. Chem.* **116**: 691, 1936.

Grant 349, 1935: Edward H. Schwab, University of Texas School of Medicine, \$200, mechanism of cardiac hypertrophy. See grant 392, 1935. Herrmann, G.; Decherd, G.; Erhard, P., and Schwab, E. H.: Normal Heart Weight/Body Weight (HW/BW) and Left to Right Ventricular (L/R) Ratios for Rabbits, *Proc. Soc. Exper. Biol. & Med.* **33**: 409, 1935. Schwab, E. H.; Herrmann, G., and Connally, J. E., Jr.: Experimental Ablation of Posterior as Contrasted to Anterior Aortic Cusp of Cardiac Hypertrophy in the Rabbit, *ibid.*, p. 410. Decherd, G.; Schwab, E. H.; Herrmann, G., and Brown, W. O.: Creatine Content of Hypertrophied Rabbits' Heart Muscle, *ibid.*, p. 521. Herrmann, G.; Decherd, G.; Schwab, E. H., and Erhard, P.: Creatine Content of Digitalized Normal and Hypertrophied Rabbit Heart Muscle, *ibid.*, p. 522. Decherd, G. M., Jr.; Herrmann, G., and Schwab, E. H., *ibid.* **34**: 864, 1936.

Grant 351, 1935: W. O. Thompson, Rush Medical College, \$300, effect of enzymatic digestion on desiccated thyroid (refund, \$250). Thompson, W. O.; Nadler, S. B.; Thompson, P. K.; Taylor, S. G. III, and Dickie, L. F. N.: A Peptide of Thyroxine with Greater Calorigenic Activity Than Desiccated Thyroid: A Consideration of Methods of Assay, *J. Clin. Investigation* **15**: 473, 1936.

Grant 352, 1935: W. J. Nungester, Northwestern University Medical School, \$250, experimental lobar pneumonia. See grant 322, 1934. Nungester, W. J.; Jourdonais, L. F., and Wolf, A. A.: The Effect of Mucin on Infections by Bacteria, *J. Infect. Dis.* 59:11, 1936. Gunn, F. D., and Nungester, W. J.: Pathogenesis and Histopathology of Experimental Pneumonia in Rats, *Arch. Path.* 21:813, 1936.

Grant 354, 1935: Roy H. Turner, Tulane University School of Medicine, \$450, physiology of peripheral vessels. Turner, R. H.; Sodeman, W. A., and Burch, G. E.: Volumetric Studies of the Circulation in a Sharply Defined Portion of the Human Finger Tip, *J. Clin. Investigation* 15:461, 1936. Turner, R. H.: Studies in the Physiology of Blood Vessels in Man, Apparatus and Methods: I. A Sensitive Plethysmograph for a Portion of the Finger, to be submitted for publication in *J. Clin. Investigation*. Sodeman, W. A.: Studies in the Physiology of Blood Vessels in Man, Apparatus and Methods: II. A Method for the Determination of the Volume of the Soft Tissue about the Terminal Phalanx of the Human Finger, to be submitted for publication in *J. Clin. Investigation*. Sodeman, W. A., Burch, G. E., and Turner, R. H.: Studies in the Physiology of Blood Vessels in Man: III. The Effect of Position of the Arm upon the Circulation of the Human Finger Tip in Health and in Certain Vascular Diseases, to be submitted for publication in *J. Clin. Investigation*.

Grant 358, 1935: John Field, Stanford University, \$200, nitrated phenols and related compounds. Field, John, and Martin, A. W.: Action du dinitrophenol 1.2.4. sur les levures lavées, *Compt. rend. Soc. de biol.* 119:458, 1935. Field, John, 2d, and Martin, A. W.: Effect of Repeated Washing on Stimulation of Yeast Respiration by 2.4 Dinitrophenol, *Proc. Soc. Exper. Biol. & Med.* 32:1285, 1935. Field, John, 2d: Effect of 4-6 Dinitro-o-Cresol on Yeast Respiration, *ibid.*, p. 1342. Field, John, 2d, and Tainter, E. G.: Some Evidence that 2.4 Dinitrophenol and 4-6 Dinitro-o-Cresol have a Common Site of Action on the Yeast Cell, *Arch. internat. de pharmacodyn. et de therap.* 54:84, 1936. See grant 400, 1936.

Grant 364, 1935: Dean A. Collins, University of Minnesota Medical School, \$200, hypertension following ligation of renal arteries in dogs. Collins, D. A.: The Phenolsulfonphthalein Renal Function Test in Dogs, *Am. J. Physiol.* 115:27, 1936. Collins, D. A.: Hypertension from Constriction of the Arteries of Denervated Kidneys, *ibid.* 116:616, 1936.

Grant 371, 1935: A. Barnett, New York University, \$300, measurement of impedance angle in thyrotoxicosis. Barnett, A., and Bagno, S.: The Physiological Mechanisms Involved in the Clinical Measure of Phase Angle, *Am. J. Physiol.* 114:366, 1936. Barnett, A., and Byron, C. S.: A Comparative Study of Impedance Angle and B. M. R. in 325 Consecutive Cases, *West. J. Surg.* 44:387, 1936.

Grant 373, 1935: Frank W. Allen, University of California, \$100, correlation of nucleotide content with glycolytic power of red blood cell in pernicious anemia. Allen, F. W.; Lucia, S. P., and Eiler, J. J.: Nucleotide Nitrogen Content of Human White Blood Cells, *Proc. Soc. Exper. Biol. & Med.* 34:609, 1936. See grant 418, 1936.

Grant 374, 1935: Charles B. Huggins, University of Chicago, \$400, relation of temperature to hematopoiesis. Huggins, C. B.; Blocksom, B. H., Jr., and Noonan, W. J.: Temperature Conditions in the Bone Marrow of Rabbit, Pigeon and Albino Rat, *Am. J. Physiol.* 115:395, 1936. Huggins, C. B., and Blocksom, B. H., Jr.: Changes in Outlying Bone Marrow Accompanying a Local Increase of Temperature Within Physiological Limits, *J. Exper. Med.* 64:253, 1936. Huggins, C. B., and Noonan, W. J.: An Increase in Reticulo-Endothelial Cells in Outlying Bone Marrow Consequent upon a Local Increase in Temperature, *ibid.*, p. 275. This work was awarded the gold medal, class 1, Scientific Exhibit, at the Kansas City session of the American Medical Association, 1936. See grant 394, 1936.

Grant 375, 1935: Heinrich Necheles, Michael Reese Hospital, Chicago, \$100, action of pitressin on gastro-intestinal motility. Necheles, Heinrich; Maskin, M.; Strauss, S.; Strauss, A. A., and Taft, E.: Effect of Posterior Pituitary Extracts on Motility of the Gastro-Intestinal Tract, *Arch. Surg.* 33:780, 1936.

Grant 383, 1935: Harry Sobotka, Mount Sinai Hospital, New York, \$300, enzymatic destruction of blood group carbohydrate (refund, \$75.10). Sobotka, Harry; Witelsky, E.; Neter, E., and Schwarz, E. S.: Relation of Blood Group Specific Substance A to the Type Specific Carbohydrate of Pneumococcus Type 1, *J. Infect. Dis.*, to be published.

Grant 391, 1935: Jessie L. King, Goucher College, \$50, effect of cortical extract on rats. See grant 276, 1933.

Grant 392, 1935: Edward H. Schwab, University of Texas School of Medicine, \$150, mechanism of cardiac hypertrophy. See grant 349, 1935.

Grant 394, 1936: Charles Huggins, University of Chicago, \$300, bone marrow. See grant 374, 1935.

Grant 395, 1936: Israel S. Kleiner, New York Homeopathic Medical College, \$350, formation of cevitamic (ascorbic) acid (refund, \$2.20). Kleiner, I. S., and Tauber, H.: Vitamin C Studies: The Requirement of Mice, the Effect of Large Quantities, and the Question of Its Formation Biologically, *Food Research* 1:399, 1936.

2. INCOMPLETE

A. Work under the grant completed, account rendered of expenses but results not published fully:

Grant 174, 1930: Alfred R. Ross, College of Medical Evangelists, Loma Linda, Calif., \$1,455, hay fever pollens in the Southwest.

Grant 179, 1930: George T. Pack, Memorial Hospital, New York, \$300, certain clinicopathologic problems of melanoma. See grant 231, 1932. Adair, F. E.: Treatment of Melanoma, *Surg., Gynec. & Obst.* 62:406, 1936.

Grant 231, 1932: George T. Pack, Memorial Hospital, New York, \$500, complete analysis of 300 cases of melanoma. See grant 179, 1932.

Grant 297, 1933: Erma A. Smith, Iowa State College, \$150, effect on the rat of sublethal amounts of illuminating gas. Smith, Erma; McMillan, E., and Mack, Lillian: Factors Influencing the Lethal Action of Illuminating Gas, *J. Indust. Hyg.* 17:18, 1935. Williams, I. R., and Smith, Erma: Blood Picture, Reproduction, and General Condition During Daily Exposure to Illuminating Gas, *Am. J. Physiol.* 110:611, 1935.

Grant 308, 1933: John L. Ulrich, Johns Hopkins University, \$250, the reflex system in the cat. See grant 372, 1935.

Grant 317, 1934: M. D. Overholser, University of Missouri, \$300, experimental growths in genital tract of monkeys and relation of anterior hypophysis to diabetes. Nelson, W. O., and Overholser, Milton D.: Effect of Oestrin Injections upon Experimental Pancreatic Diabetes in the Monkey, *Proc. Soc. Exper. Biol. & Med.* 32:150, 1934. Overholser, M. D., and Nelson, W. O.: Migration of Nuclei in Uterine Epithelium of Monkey Following Prolonged Estrin Injections, *Proc. Soc. Exper. Biol. & Med.* 34:839, 1936. Nelson, W. O., and Overholser, M. D.: The Effect of Estrogenic Hormone on Experimental Pancreatic Diabetes in the Monkey, *Endocrinology* 20:473, 1936.

Grant 353, 1935: Frank R. Menne, University of Oregon Medical School, \$500, metabolism of cholesterol in rabbits (refund, \$10.78).

Grant 360, 1935: A. M. Wright, J. J. Mulholland and F. W. CoTui, New York University, \$300, physiology of sympathectomized dogs (refund, \$1.30).

Grant 361, 1935: P. L. Heitmeyer, University of Oregon Medical School, \$100, experimental uterine ovarian implants.

Grant 362, 1935: Lloyd H. Ziegler and Arthur Knudson, Albany Medical College, \$100, activity after recovery from rickets.

Grant 363, 1935: Rachel E. Hoffstadt, University of Washington, \$100, protein and carbohydrate fractions of *Staphylococcus aureus*.

Grant 369, 1935: Harold Jeghers, Boston University School of Medicine, \$150, vitamin A deficiency in certain diseases.

Grant 372, 1935: John L. Ulrich, Johns Hopkins University, \$450, cerebral functions in the action of antagonistic muscles. See grant 308, 1933.

B. ACTIVE WORK STILL IN PROGRESS

Grant 254, 1932: J. Lisle Williams, McCormick Institute, Chicago, \$200, decreased dextrose tolerance in acute infectious diseases.

Grant 277, 1933: Gustav Zechel, University of Illinois College of Medicine, \$260, study of growing malignant cells by moving photomicrographs. Zechel, Gustav, and Morgenstern, O.: A Timing Device for Talking Motion Pictures, *Science* 81:23, 1935.

Grant 286, 1933: F. H. Pike, Columbia University, \$600, the effects of successive experimental lesions of the nervous system.

Grant 309, 1933: Carroll L. Birch, University of Illinois School of Medicine, \$300, assay of urine for sex hormone of the anterior pituitary.

Grant 310, 1934: Lay Martin, Johns Hopkins University, \$150, study of gastric juice.

Grant 324, 1934: William deB. MacNider, University of North Carolina, \$285, study of artificial circulation in the kidney.

Grant 337, 1934: James L. O'Leary, Washington University, \$245, Loven reflexes.

Grant 340, 1934: Louis S. Goodman and Arthur J. Geiger, Yale University, \$200, further study of antianemic principle. See grants 333, 1934, and 382, 1935.

Grant 343, 1934: John Guttman, Post-Graduate Medical School and Hospital, \$400, relation between electrical disturbances in cochlea and the sensation of hearing.

Grant 338, 1934: W. W. Brandes, Baylor University, \$150, the effect of acidosis on antibodies and resistance to infection.

Grant 344, 1934: Paul L. Day and W. C. Langston, University of Arkansas School of Medicine, \$300, effect of withdrawal of vitamin G from diet of monkeys.

Grant 345, 1934: Emile Holman, Stanford University School of Medicine, \$400, study by Frederick Fender of prolonged stimulation of the nervous system. See grant 377, 1935.

Grant 346, 1934: William Antopol, Mount Sinai Hospital, New York, \$250, relationship of acetylcholine to carbohydrate metabolism. Tuchman, L.; Schiffrin, A., and Antopol, W.: Blood Amylase Response to Acetyl-Beta-Methylcholine Chloride in Pancreatized Dogs, *Proc. Soc. Exper. Biol. & Med.* 33:142, 1935. Schiffrin, A.; Tuchman, L., and Antopol, W.: Blood Amylase Response to Acetyl-Beta-Methylcholine Chloride in Rabbits, *Proc. Soc. Exper. Biol. & Med.* 34:539, 1936.

Grant 348, 1935: Phillips Thygeson, State University of Iowa, \$400, trachoma and "inclusion virus" disease of the genito-urinary tract. Thygeson, Phillips, and Mengert, W. F.: The Virus of Inclusion Conjunctivitis, *Arch. Ophthalm.* 15:377, 1936.

Grant 350, 1935: Frederic A. Gibbs, Harvard University School of Medicine, \$100, fiber system in the cat's brain concerned in convulsions.

Grant 355, 1935: Royall M. Calder, San Antonio, Texas, \$150, mechanism of pneumococcus inflammation.

Grant 356, 1935: Jay C. Davis, University of Minnesota, \$500, coronary flow and lesions of the aortic valves.

Grant 365, 1935: Ludwig A. Emge, Stanford University School of Medicine, \$500, effect of castration on malignant tumors. See grant 341, 1934.

Grant 366, 1935: G. E. Burget, University of Oregon Medical School, \$500, physiology of cardiac portion of stomach. Burget, G. E., and Zeller, W. E.: A Study of the Cardia in Unanesthetized Dogs, *Proc. Soc. Exper. Biol. & Med.* 34:433, 1936.

Grant 367, 1935: Robert Gault and A. C. Ivy, American Institute for the Deaf-Blind, Evanston, Ill., \$600, mechanical stimulation of the vibrotactile organs. See grant 412, 1936.

Grant 368, 1935: Felix Saunders, University of Chicago, \$250, growth factors for bacteria. See grant 399, 1936.

Grant 370, 1935: Richard L. Crouch, University of Missouri, \$500, connections of diencephalon.

Grant 377, 1935: Frederick A. Fender, Stanford University School of Medicine, \$600, prolonged stimulation of parts of the nervous system. See grant 345, 1934.

Grant 378, 1935: Wallace M. Yater, Georgetown University Hospital, Washington, D. C., histopathologic basis of "bundle branch" block.

Grant 379, 1935: Victor C. Myers (Donald E. Bowman), Western Reserve Medical School, \$650, chemical test for pregnancy.

Grant 380, 1935: N. W. Popoff, Highland Hospital, Rochester, N. Y., \$600, arteriovenous anastomosis.

Grant 381, 1935: John R. Murlin, University of Rochester Medical School, \$600, testis hormone. See grant 414, 1936. Kochakian, C. D., and Murlin, J. R.: The Relationship of the Synthetic Male Hormone, Androstendion, to the Protein and Energy Metabolism of Castrate Dogs, and the Protein Metabolism of a Normal Dog, *Am. J. Physiol.* **117**: 642, 1936.

Grant 382, 1935: L. Goodman, A. J. Geiger and L. Claiborn, Yale University, \$250, antianemic principle. See grants 333 and 340, 1934.

Grant 385, 1935: Erwin Brand and G. F. Cahill, New York State Psychiatric Institute and Hospital, \$200, cystinuria.

Grant 386, 1935: E. V. McCollum, Johns Hopkins University, \$150, adaptation of the eyes to subdued light and its relation to vitamin A (refund, \$19.65).

Grant 387, 1935: George D. Snell, Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, \$500, hereditary changes in germ cells from x-rays (refund, \$20).

Grant 388, 1935: Tracy J. Putnam, Boston City Hospital, Boston, \$150, effect of low voltage current on nervous system.

Grant 389, 1935: Tracy J. Putnam, Boston City Hospital, Boston, \$150, mechanism of cortical atrophy in dementia paralytica.

Grant 390, 1935: Abraham White, Yale University, \$100, chemistry and metabolism of the sulfur of proteins (refund, \$8.25). See grant 429, 1936. White, A., and Fishman, J. B.: The Formation of Taurine by the Decarboxylation of Cysteic Acid, *J. Biol. Chem.* **116**: 457, 1936. field, Ill., \$100, available dextrose in certain common foodstuffs.

3. DISCONTINUED (NO RESULTS PUBLISHED)

Grant 287, 1933: Thomas D. Masters, Springfield Hospital, Springfield, Ill., \$100, available dextrose in certain common foodstuffs.

Grant 306, 1934: Charles H. Frazier, Hospital of University of Pennsylvania, \$751, autonomic representation of the urinary bladder in the cerebral cortex and in hypothalamus (refund, \$476.94).

Grant 376, 1935: Herbert F. Thurston, University of Indiana School of Medicine, \$300, roentgen ray in treatment of gas gangrene (refund, \$300).

Grant 384, 1935: J. Louis Weller, George Washington University, \$108, action of certain substances on hematopoietic tissue of the chick (refund, \$108).

Report of Committee on Therapeutic Research

The Committee on Therapeutic Research, a standing committee of the Council on Pharmacy and Chemistry, encourages scientific investigations in the field of therapeutics by providing funds for the prosecution of necessary research.

During the year 1936 the Committee issued twenty-seven new grants. A detailed list of these grants, together with a list of publications during 1936, and of unexpired grants made before Jan. 1, 1936, will be found in the appendix to this report.

The following is a list of the investigations conducted with the assistance of grants made by the Committee on Therapeutic Research, reports of which were published during 1936:

1. Rat Test for Drug Addiction, Eugene J. Stanton: *Proceedings of the Society for Experimental Biology and Medicine*, April 1936, p. 340.

2. A Modified Pigeon Method for the Bioassay of Anti-Pernicious Anemia Liver Extracts, G. E. Wakerlin, H. D. Bruner and J. M. Kinsman: *Journal of Pharmacology and Experimental Therapeutics* **58**: 1 (Sept.) 1936.

3. Presence in Normal Human Urine of a Reticulocyte-Stimulating Principle for the Pigeon, G. E. Wakerlin and H. D. Bruner: *Archives of Internal Medicine* **57**: 1032 (May) 1936.

4. The Relation of the Reticulocytogenic Urine Principle to the Anti-Pernicious Anemia Liver Principle, G. E. Wakerlin: *Proceedings of the Central Society for Clinical Research*, November 1936, p. 46.

5. A Partially Purified Liver Extract Therapeutically Effective in Pernicious Anemia, Y. Subbarow, Bernard M. Jacobson and Cyrus H. Fiske: *New England Journal of Medicine* **214**: 194 (Jan. 30) 1936.

6. Chemical Studies of the Pernicious Anemia Principle in Liver, Bernard M. Jacobson and Y. Subbarow: *Journal of Biological Chemistry* **114**: 102 (May) 1936.

7. A Note on the Guinea-Pig Method of Assay of Liver Extract, Bernard M. Jacobson: *British Journal of Experimental Pathology* **17**: 307 (Aug.) 1936.

8. Studies of the Pernicious Anemia Principle in Liver: III. The Isolation and Properties of a Substance with Primary Therapeutic Activity, Y. Subbarow, Bernard M. Jacobson and Vilma Prochownik: *Journal of the American Chemical Society* **58**: 2234 (Nov.) 1936.

9. The Biological Assay of Estrogenic Substances in the Human by the Use of Vaginal Smears, Henry B. Richardson, Ephraim Shorr and George N. Papanicolaou: *Transactions of the Association of American Physicians* **51**: 213, 1936.

10. The Action of Ovarian Follicular Hormone in the Menopause, as Indicated by Vaginal Smears, George N. Papanicolaou and Ephraim Shorr: *American Journal of Obstetrics and Gynecology* **31**: 806 (May) 1936.

11. Vaginal Smears During Spontaneous Symptomatic Relief in the Menopause, Ephraim Shorr and George N. Papanicolaou: *Journal of Clinical Investigation* **15**: 454 (July) 1936.

12. Chemical Studies of Acute Poisoning from Mercury Bichloride, Torald Sollmann and Nora E. Schreiber: *Archives of Internal Medicine* **57**: 46 (Jan.) 1936.

13. Further Studies Dealing with the Sublingual Absorption of Drugs, Robert P. Walton: *Journal of Pharmacology and Experimental Therapeutics* **57**: 148 (June) 1936.

14. The Ineffectiveness of Drugs upon Collateral Flow After Experimental Coronary Occlusion in Dogs, Carl J. Wiggers and Harold D. Green: *American Heart Journal* **11**: 527 (May) 1936.

15. The Influence of Cortico-Adrenal Extract on the Course of Bacterial Intoxications in Guinea-Pigs, Richard W. Whitehead and Charles A. Fox: *Endocrinology* **20**: 93 (Jan.) 1936.

16. Relation of the Adrenal Glands to Immunological Processes, Charles A. Fox and R. W. Whitehead: *Journal of Immunology* **30**: 51 (Jan.) 1936.

17. The Production of a Deficiency Involving Cystine and Methionine by the Administration of Cholic Acid, Abraham White: *Journal of Biological Chemistry* **112**: 503 (Jan.) 1936.

18. The Availability of dl-Amino-N-Methylhistidine for Growth, Jacob B. Fishman and Abraham White: *Journal of Biological Chemistry* **113**: 175 (Feb.) 1936.

19. Sugar Alcohols: V. Chemical Constitution and Sweet Taste, C. Jelleff Carr, Frances F. Beck and John C. Krantz Jr.: *Journal of the American Chemical Society* **58**: 1394 (Aug.) 1936.

20. Acute Toxicity of Certain Sugar Alcohols and Their Anhydrides, Frances F. Beck, C. Jelleff Carr and John C. Krantz Jr.: *Proceedings of the Society for Experimental Biology and Medicine* **35**: 98 (Oct.) 1936.

21. Diseases of the Nails, Cleveland White: *Urologic and Cutaneous Review* **40**: 562 (Aug.) 1936.

22. Relative Actions of Dihydromorphinone Hydrochloride and Morphine Sulfate on the Excised Ureter and Bell's Muscle, Charles M. Gruber: *Proceedings of the Society for Experimental Biology and Medicine* **33**: 532 (Jan.) 1936.

23. The Effect of Methyl-Amino Methyl Heptene (Octin) upon the Intact Intestine in the Nonanesthetized Dog, Charles M. Gruber: *Journal of Pharmacology and Experimental Therapeutics* **56**: 284 (March) 1936.

24. The Action of Epinephrine, Tyramine and Ephedrine on the Small Intestine of the Unanesthetized Dog, Before and Following the Administration of Cocaine, Charles M. Gruber: *Journal of Pharmacology and Experimental Therapeutics* **57**: 347 (Aug.) 1936.

25. Experimental Radium Poisoning: I. Bone Marrow and Lymph Node Changes in Rabbits, Produced by Oral Administration of Radium Sulfate, Maurice Rosenthal and Edwin J. Grace: *American Journal of the Medical Sciences* **191**: 607 (May) 1936.

26. Further Studies in Experimental Granulopenia, with Particular Reference to Sulfhydryl (Glutathione) Metabolism in Blood Dyscrasias, Francis P. Parker and Roy R. Kracke: *American Journal of Clinical Pathology* **6**: 41 (Jan.) 1936.

27. Dilation of the Coronary Vessels by Certain Organic Extracts and Drugs, Charles W. Greene: *Journal of Pharmacology and Experimental Therapeutics* **57**: 98 (May) 1936.

28. An Analysis of the Relations of the Coronary Constrictor and Dilator Nerves in the Cervical Vagosympathetic of the Dog, Charles W. Greene: *American Heart Journal* **11**: 592 (May) 1936.

29. The Nervous Control of the Coronary Circulation and Its Clinical Significance, Charles W. Greene: *Southern Medical Journal* **29**: 478 (May) 1936.

30. Chemotropism of Leukocytes in Relation to Their Rate of Locomotion, Harold M. Dixon and Morton McCutcheon: *Proceedings of the Society for Experimental Biology and Medicine* **34**: 173 (March) 1936.

31. Chemotropic Reactions of Polymorphonuclear Leukocytes to Various Micro-Organisms, Morton McCutcheon and Harold M. Dixon: *Archives of Pathology* **21**: 749 (June) 1936.

32. Researches on Pyrimidines: CLIV. Pyrimidine Side Chain Reactions Useful for the Synthesis of 1, 3-Diazines Related Structurally to Vitamin B₁, Anne Litzinger and Treat B. Johnson: *Journal of the American Chemical Society* **58**: 1936 (Oct.) 1936.

33. Researches on Pyrimidines: CLV. The Synthesis of Thymine, amine and Its Conversion into Uracil, Treat B. Johnson and Anne Litzinger: *Journal of the American Chemical Society* **58**: 1940 (Oct.) 1936.

34. Experimental Therapy in Coccidioid Granuloma, Harold C. Sox and Ernest C. Dickson: *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* 106:777 (March 7) 1936.

35. The Relation of Leucine, Isoleucine, and Norleucine to Growth, Madelyn Womack and William C. Rose: *Journal of Biological Chemistry* 116:381 (Nov.) 1936.

36. Effect of Carotene and Vitamin A on Patients with Diabetes Mellitus: III. The Effect of the Daily Administration of Carotene on the Blood Carotene of Normal and Diabetic Individuals, Elaine P. Ralli, Arthur C. Pariente, Harold Brandaleone and Sidney Davidson: *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* 106:1975 (June 6) 1936.

37. A Summary of Studies on the Effect of Ferric Chloride on Tuberculous Rabbits, Vally Menkin: *Proceedings of the Society for Experimental Biology and Medicine* 34:262 (March) 1936.

38. Significance of Carbohydrate Metabolism and Local Acidosis in Inflammation, Vally Menkin and Charlotte R. Warner: *Proceedings of the Society for Experimental Biology and Medicine* 34:594 (June) 1936.

39. Experimental Siderosis: III. Spectroscopic Studies of Iron-Containing Pigment, Egon Lorenz and Vally Menkin: *Archives of Pathology* 22:82 (July) 1936.

40. Studies on Inflammation: XII. Mechanism of Increased Capillary Permeability—A Critique of the Histamine Hypothesis, Vally Menkin: *Journal of Experimental Medicine* 64:485 (Sept. 1) 1936.

41. Paralyzing Effects of Sodium Citrate on the Cardiac Vagus and on Heart Muscle of the Cat, George D. Shafer and Jefferson M. Crismon: *Journal of Pharmacology and Experimental Therapeutics* 58:274 (Nov.) 1936.

42. The Alimentary Fate of Hemin in Man, Franklin C. Bing, Franklin A. Benes and Donald G. Remp: *Proceedings of the American Society of Biological Chemists, Journal of Biological Chemistry*, May 1936.

43. A Study of Blood Constituents in Pollinosis With and Without Treatment, M. L. Hathaway, B. Z. Rappaport, C. I. Reed and H. C. Struck: *Journal of Allergy* 8:1 (Nov.) 1936.

44. Total Plasmapheresis, John B. Stanbury, Edna Warweg and William R. Amberson: *American Journal of Physiology* 117:230 (Oct.) 1936.

During 1936 the following grants were made:

Grant 279: Norman A. David, assistant professor of pharmacology, University of Cincinnati College of Medicine, \$65, to investigate the effects of carbarsone and other pentavalent arsenicals on the optic nerve.

Grant 280: John P. Peters, professor of medicine, Yale University School of Medicine, \$200, to investigate by means of intravenous pyelography the state of ureters and kidneys in a large series of patients after delivery and subsidence of acute signs of toxemia.

Grant 281: O. W. Barlow, formerly assistant professor of pharmacology, Western Reserve University School of Medicine, \$125, to investigate circulatory effects of metrazol under conditions of anesthesia with ether as well as under the influence of hypnotics.

Grant 282: Arthur W. Grace, Department of Medicine, Cornell University Medical College, \$250, to investigate the effect of x-ray and Frei vaccine therapy in artificially inoculated lymphogranuloma inguinale in guinea-pigs.

Grant 283: Louis N. Katz, physiologist and director of cardiovascular research, Nelson Morris Memorial Institute for Medical Research, Michael Reese Hospital, Chicago, \$200, to investigate the action of drugs on coronary circulation.

Grant 284: Mary E. Collett, Flora Stone Mather College, Western Reserve University, \$60, to investigate the effect of the female sex hormone on the hot flashes and the basal metabolism of ovariectomized women.

Grant 285: Morton McCutcheon, associate professor of pathology, University of Pennsylvania School of Medicine, \$150, to investigate the chemotropism of leukocytes.

Grant 286: Vally Menkin, Department of Pathology, Harvard University Medical School, \$200, to investigate inflammation and tuberculosis in relation to immunity.

Grant 287: M. L. Tainter, professor of pharmacology, Stanford University School of Medicine, \$250, to investigate sympathomimetic amines.

Grant 288: Louis Goodman, Department of Pharmacology and Toxicology, Yale University School of Medicine, \$150, to investigate the effects of histidine injections on gastric physiology.

Grant 289: Carl C. Pfeiffer, Department of Pharmacology, University of Chicago, \$225, to investigate the possible amino acids present in the *Trypanosoma lewisi* antibody.

Grant 290: Edward J. Van Liere, acting dean and professor of physiology, West Virginia University School of Medicine, \$150, to investigate the effect of ephedrine on absorption from the small intestine.

Grant 291: J. F. McClendon, professor of physiologic chemistry, University of Minnesota Medical School, \$200, to investigate blood iodine in different types of goiter.

Grant 292: W. L. Bradford, associate professor of pediatrics, University of Rochester School of Medicine, \$150, to investigate the value of immune blood in whooping cough.

Grant 293: F. C. Koch, chairman Department of Physiological Chemistry and Pharmacology, University of Chicago, \$250, to investigate provitamin D and vitamin D.

Grant 294: Harald G. O. Holck, associate professor of pharmacology, University of Nebraska College of Medicine, \$150, to investigate sex difference in white rats in tolerance to certain barbiturates.

Grant 295: Torald Sollmann, dean and professor of pharmacology and materia medica, Western Reserve University School of Medicine, and Albert Gilbert, Western Reserve University School of Medicine, \$150, to investigate the microscopic reactions of the bronchioles to drugs and anaphylaxis.

Grant 296: M. M. Wintrobe, Johns Hopkins Hospital, \$150, to investigate the blood picture of pernicious anemia.

Grant 297: Melvin Dresbach, Harvard University Medical School, \$250, to investigate the emetic effect of some of the digitalis bodies.

Grant 298: Kenneth W. Thompson, Department of Physiology, Yale University School of Medicine, \$200, to investigate the effects of the thyroid stimulating hormone pituitary; its relationship to other substances in the possible control of hyperthyroidism.

Grant 299: Everett Idris Evans, Department of Pharmacology, University of Chicago, \$150, to investigate prolactin.

Grant 300: Victor E. Hall, associate professor of biology, Stanford University School of Medicine, \$200, to investigate the mechanism of the inhibition of the metabolic stimulating action of dinitrophenol by exposure to low environmental temperatures.

Grant 301: Maurice Rosenthal, instructor in pathology, Long Island College of Medicine, \$200, to investigate radium poisoning.

Grant 302: Mary E. Collett, Flora Stone Mather College, Western Reserve University, \$200, to investigate the effect of the female sex hormone on the hot flashes and the basal metabolism of ovariectomized women.

Grant 303: Arnold De M. Welch, Department of Pharmacology, Washington University School of Medicine, \$200, to investigate the action of choline and betaine in the metabolism of fat.

Grant 304: Howard B. Lewis, professor of biological chemistry, University of Michigan Medical School, \$175, to investigate selenium salts.

Grant 305: Beverly Douglas, assistant dean and associate professor of surgery, Vanderbilt University School of Medicine, \$250, to investigate the pneumatic (transparent rubber jacket) system of treating extensive wounds.

The following grants were issued before Jan. 1, 1936. In some cases the grant has expired and an unexpended balance remains; or the work is not yet completed; or not yet published.

Grant 102: C. W. Greene, professor of physiology and pharmacology, University of Missouri, \$250, to investigate the distribution of nitrous oxide and oxygen in the blood during anesthesia.

Grant 119: Nicholas Kopeloff, research associate in bacteriology, New York State Psychiatric Institute and Hospital, \$100, to investigate bacillus acidophilus milk for the prevention and treatment of summer diarrhea in babies.

Grant 152: C. W. Greene, professor of physiology and pharmacology, University of Missouri, \$300, to investigate the reaction of the coronary system to drugs.

Grant 164: E. L. Jackson, associate professor of pharmacology, Emory University School of Medicine, \$200, to investigate the antagonism between sodium barbital and insulin.

Grant 194: Sarah A. Riedman, College of Physicians and Surgeons, Columbia University, \$200, to investigate the effect of a high fat or ketogenic diet on the susceptibility of animals to convulsions of experimental origin.

Grant 200: Walter Bauer, Massachusetts General Hospital, the Robert W. Lovett Memorial Foundation of the Harvard University Medical School, \$250, to investigate the anatomy and physiology of normal joints, with special reference to rheumatoid arthritis.

Grant 201: George R. Cowgill, associate professor of physiologic chemistry, Sterling Hall of Medicine, Yale University, \$250, to investigate vitamin B in relation to morphine addiction.

Grant 210: C. I. Reed, associate professor of physiology, University of Illinois College of Medicine, \$200, to investigate the use of viosterol 10,000 X in seasonal hay fever.

Grant 214: E. A. Park, professor of pediatrics, and J. A. Pierce, Johns Hopkins University School of Medicine, \$200, to investigate the reaction of cartilage.

Grant 219: Torald Sollmann, professor of pharmacology, and Harold N. Cole, associate professor of dermatology and syphilology, Western Reserve University School of Medicine, \$100, to investigate the epidemic factor in mercurial salivation.

Grant 221: John G. Reinhold, Department of Public Health, Philadelphia General Hospital, \$250, to investigate the action of aminocacetic acid (glycine) in progressive muscular dystrophy.

Grant 222: Eugene U. Still, assistant professor of physiology, University of Chicago, \$250, to investigate the changes in the metabolism of the pancreas.

Grant 223: Clinton H. Thienes, professor of pharmacology, and Lawrence E. Detrick, Department of Pharmacology, University of Southern California School of Medicine, \$200, to investigate withdrawal phenomena in morphine addicted animals.

Grant 228: Henry G. Barbour, associate professor of pharmacology and toxicology, Yale University School of Medicine, \$250, to investigate metabolism and water exchange in morphine habituation.

Grant 232: George R. Cowgill, associate professor of physiologic chemistry, Yale University School of Medicine, \$250, to investigate the heart in vitamin B deficiency.

Grant 236: Charles W. Greene, professor of physiology and pharmacology, University of Missouri School of Medicine, \$100, to investigate the pharmacology of the so-called specific coronary dilator drugs.

Grant 238: Roy R. Kracke, professor of pathology, Emory University School of Medicine, \$250, to investigate the effect of the oxidation products of aminopyrine and related drugs on the leukocyte counts of rabbits.

Grant 239: John R. Murlin, director and professor of physiology, University of Rochester School of Medicine, \$100, to investigate the absorption of insulin from the alimentary tract.

Grant 247: Arthur W. Grace, Department of Medicine, Cornell University Medical College, \$250, to investigate the use of antimonial compounds in the treatment of lymphogranuloma inguinale.

Grant 248: Fred C. Koch, chairman of the Department of Physiological Chemistry and Pharmacology, University of Chicago, \$250, to investigate the male sex hormone.

Grant 249: J. Percy Baumberger, associate professor of physiology, Stanford University, Department of Physiology, \$200, to investigate the occurrence and oxidation-reduction potential of pigments in tumor cells.

Grant 250: A. R. McIntyre, professor of pharmacology, University of Nebraska College of Medicine, \$100, to investigate the effects of the digitaloid bodies on the metabolism of dextrose by the cardiac musculature.

Grant 251: Dr. Bernard Fantus, professor of therapeutics, University of Illinois College of Medicine, \$100, to investigate the titration of the antitoxic value of serum of patients who have received tetanus antitoxin.

Grant 254: C. W. Edmunds, professor of materia medica and therapeutics, University of Michigan Medical School, \$200, to investigate the action of the drugs in the digitalis group in animals injected with diphtheria toxin.

Grant 257: O. W. Barlow, formerly assistant professor of pharmacology, Western Reserve University School of Medicine, \$150, to investigate analeptics versus barbiturates.

Grant 258: Claus W. Jungeblut, professor of bacteriology, Columbia University College of Physicians and Surgeons, \$250, to investigate vitamin C versus diphtheria.

Grant 259: O. W. Barlow, formerly assistant professor of pharmacology, Western Reserve University School of Medicine, \$100, to investigate the effects of parasympathetic drugs on the intestine.

Grant 261: Robert P. Walton, assistant professor of pharmacology, Tulane University of Louisiana School of Medicine, \$100, to investigate the absorption of drugs through the oral mucosa.

Grant 262: Victor E. Hall, associate professor of physiology, Stanford University, \$125, to investigate the mechanism of inhibition of the metabolic stimulating action of dinitrophenol by exposure to low environmental temperatures.

Grant 263: H. A. Shoemaker, associate professor of biochemistry and pharmacology, C. E. Clymer, professor of clinical surgery, and Henry H. Turner, University of Oklahoma School of Medicine, \$150, to investigate the blood cholesterol and iodine values in thyroid disease and their alteration by treatment.

Grant 264: Detlev W. Bronk, Johnson professor of biophysics, University of Pennsylvania School of Medicine, \$200, to investigate the action of various drugs on the autonomic centers.

Grant 266: F. C. Koch, chairman Department of Physiological Chemistry and Pharmacology, University of Chicago, \$250, to investigate the antirachitic potency of irradiated sterols other than ergosterol.

Grant 268: Walter E. Hamburger, assistant professor of pharmacology, Western Reserve University School of Medicine, \$250, to investigate the mechanism of morphine action, with special reference to the excitement in cats.

Grant 269: Francis G. Blake, Sterling professor of medicine, and Marion E. Howard, Sterling professor of medicine, Yale University School of Medicine, \$50, to investigate the use of artificial pneumothorax in the treatment of lobar pneumonia.

Grant 270: Elaine P. Ralli, assistant professor of medicine, New York University College of Medicine, \$250, to investigate the effect of carotene on the blood vitamin A.

Grant 272: Ephraim Shorr, assistant professor of medicine, Cornell University Medical College, \$150, to investigate the value of various ovarian preparations.

Grant 273: Marston T. Bogert, professor of chemistry, Columbia University, \$100, to investigate the chemistry and pharmacology of the quinazoline group.

Grant 275: Roberta Hafkesbring, associate professor of physiology, Woman's Medical College of Pennsylvania, \$200, to investigate the effects of sodium barbital and other hypnotics.

Grant 276: Eugene Stanton, Department of Pharmacology, Western Reserve University School of Medicine, \$150, to investigate the addiction, tolerance and abstinence to various narcotics in animals, especially rats.

Grant 277: Katharine Henderson, Department of Pharmacology, Western Reserve University School of Medicine, \$300, to investigate the excretion of bismuth.

Grant 278: William H. Lewis Jr., assistant clinical professor of medicine, and Arthur C. de Graff, professor of therapeutics, New York University College of Medicine, \$150, to investigate the function of the heart in relation to age.

TREASURER'S REPORT

Report of the Treasurer of the American Medical Association for the Year Ending December 31, 1936

Reserve invested as at December 31, 1935.....	\$2,090,414.69	
Bonds Purchased (Cost).....	251,812.50	
	<u>2,342,227.19</u>	
Less Bonds Called.....	88,705.88	\$2,253,521.31
Balance for Investment December 31, 1935....	147,063.44	
Interest on Investments.....	80,969.60	
	<u>228,033.04</u>	
Less:		
Transfer to General Fund.....	\$150,000.00	
Investments Purchased	71,162.29	221,162.29
	<u>6,870.75</u>	
Invested and Uninvested Reserve as at December 31, 1936.....		<u>\$2,260,392.06</u>

DAVIS MEMORIAL FUND

Balance in Fund December 31, 1935.....	\$6,909.16
1936 Interest on Bank Balance.....	104.02
Total Fund as at December 31, 1936, on Deposit..	<u>\$ 7,013.18</u>

HERMAN L. KRETSCHMER, Treasurer.

AUDITOR'S REPORT

January 23, 1937.

To the Board of Trustees,

American Medical Association, Chicago, Illinois.

Dear Sirs:

In accordance with your instructions, we have made an examination of the Balance Sheet of the American Medical Association, Chicago, Illinois, as at December 31, 1936, and of the Income Account for the year 1936. In connection therewith, we examined or tested accounting records of the Association and other supporting evidence and obtained information and explanations from officers and employees of the Association; we also made a general review of the accounting methods and of the operating and income accounts for the year, but we did not make a detailed audit of the transactions. We now submit our report on the examination, together with related statements as enumerated in the index appended hereto.

In our opinion, based on such examination, the accompanying Balance Sheet and relative Income Account fairly present the position of the Association as at December 31, 1936, and the result of its operations for the year ended on that date, subject to the following qualifications and observations:

(1) The inventories of Materials, Supplies and Work in Progress in the amount of \$84,223.59 are stated in accordance with affidavits sworn to by responsible officials of the Association and have not been confirmed by us in any way.

(2) In accordance with the established practice of the Association, no provision has been made for (a) accrued interest on bonds, (b) membership dues unpaid, (c) accrued salaries and wages, and (d) accrued property taxes for the year 1936.

(3) Subscriptions paid in advance represent an estimated amount based on cash received for subscriptions for the year 1937, received in the month of December 1936. This conforms with the method used in prior years.

(4) Advance payments on publications represent an estimated amount of prepaid subscriptions to Hygeia \$125,789.24 plus \$12,116.99 received in advance for January advertising and Directory sales and service.

(5) During the year the Association completed the remodeling of the main building and the addition of two floors; and at December 31, 1936, all of the buildings, including two storage buildings, the cost of which had been previously written off, were appraised by Holabird and Root, resulting in an increase in value of \$124,481.59 over the book value at December 31, 1936, which was placed on the books at that date. In accordance with the previous practice of the Association depreciation has been computed at the rate of 2½% on the main building and on machinery and equipment at the rate of 5% on the diminishing book values prior to the appraisal.

We have received a letter from Messrs. Loesch, Scofield, Loesch and Burke, acting as Attorneys for the Association, stating that at December 31, 1936, there were two lawsuits pending against the Association, one filed by Dr. Jean Paul Fernel in the amount of \$1,000,000.00 for alleged libel, and the other filed by Herbert Edwin Soule, Helen B. Ickler and Julius Ickler to enjoin the Association from performing certain

functions specified in the complaint. The attorneys stated in their letter that it was their opinion they would eventually defeat both suits. We have also received a certificate from an official of the Association stating that at December 31, 1936, there were no contingent liabilities except the lawsuits here referred to.

Fidelity insurance is carried against the undermentioned officers and employees of the Association in the amount here stated:

Dr. Olin West, General Manager.....	\$10,000.00
Dr. Herman L. Kretschmer, Treasurer.....	10,000.00
E. A. Hoffman, Cashier.....	10,000.00
J. E. Hartigan, Assistant Cashier.....	2,000.00
Sundry Employees (eight, \$1,000.00 each).....	8,000.00
Total Fidelity Insurance.....	<u>\$40,000.00</u>

We have pleasure in reporting that the books are well maintained and that every facility was afforded us for the proper conduct of the examination.

Yours truly, PEAT, MARWICK, MITCHELL & Co.

INDEX TO STATEMENTS

REPORT OF THE JUDICIAL COUNCIL

To the Members of the House of Delegates of the American Medical Association:

During the past year the usual number of requests for advice on ethical questions, information on economic subjects and complaints concerning both have been handled by the Council with varying degrees of satisfaction to the inquirers. Economic subjects invariably involve ethical questions and it is apparent that in many instances, somewhere behind the correspondent's problem, is an effort, sometimes on his part and sometimes on the part of others, to evade the principles of conduct established for our guidance. These principles have proved broad and comprehensive enough to cover satisfactorily any situation that has arisen if the effort to follow the principles has honestly been made; but because this has not always been the case the Judicial Council deems it expedient to clarify by certain changes and additions, which will later be offered as amendments, some paragraphs in our printed Principles of Medical Ethics.

Article VI refers to "Compensation." Section 2 of that article is headed "Contract Practice." The first paragraph of the section reads as follows:

It is unprofessional for a physician to dispose of his services under conditions that make it impossible to render adequate service to his patient or which interfere with reasonable competition among the physicians of a community. To do this is detrimental to the public and to the individual physician, and lowers the dignity of the profession.

To one seeking only high ideals in medical practice, this statement would be taken as covering all medical practice; but to one endeavoring to justify a practice not up to the standard of such an ideal, the interpretation may and has been made that because the section is captioned "Contract Practice" and has to do principally with that subject it has no application except as to contract practice.

In the same section, contract practice is defined as follows:

By the term "contract practice" as applied to medicine is meant the carrying out of an agreement between a physician or a group of physicians, as principals or agents, and a corporation, organization or individual, to furnish partial or full medical services to a group or class of individuals for a definite sum or a fixed rate per capita.

If it is contract practice to care for a group or class of individuals for a definite sum or a fixed rate per capita as a basis of payment for the group, it is equally contract practice if the payment is based on an agreed fee schedule.

In the same section, the next paragraph enumerates certain features or conditions which, if present, make a contract unethical, among which is "5. When free choice of a physician is prevented." The phrase "free choice of physician" is more and more frequently used and there is a general understanding of what the phrase means. Actually no person can have an absolutely free choice for many reasons, and if his freedom of choice is not absolute then it is not free but limited. Chapter II, section 3, of Principles of Medical Ethics states: "A physician is free to choose whom he will serve." Therefore the physician whom the patient chooses may decline to serve when he is chosen. Or the chosen physician may be unavailable for many reasons. As the Judicial Council has often to interpret this phrase, it seems proper to define the term as applied to contract practice and include the definition in the paragraph devoted to that subject. An amendment will be presented at the proper time for action by the House.

RULES OF COUNTY SOCIETIES

The Judicial Council notes a tendency which, while not widespread, appears to be growing, of county societies establishing certain "rules of conduct" to control membership and basing disciplinary measures on violation of such rules. These "rules of conduct" are usually in the form of specific laws forbidding certain defined actions. They are based on the principles enunciated in the Principles of Medical Ethics, which principles in all instances so far coming to the attention of the Council are sufficient in scope to cover the situations sought to be corrected. Such rules, usually drawn to meet a particular condition that has caused an inflamed sentiment against certain individuals or groups, are adopted hastily with little consideration of anything except to correct the situation immediately at hand. No rules of conduct adopted by county medical societies

have as yet caused embarrassment to the Judicial Council in its endeavors to protect equitably membership in the American Medical Association. The question is likely to arise soon, however, as to whether a member of the American Medical Association may be deprived of membership for infraction of a rule of conduct not actually involving unethical conduct as presented in the Principles of Medical Ethics. The Judicial Council senses danger in the development of two ethical standards of possible injustice to the membership of this organization in the adoption of rules of conduct designed by county societies to supplement the principles of medical ethics established by the House of Delegates.

COOPERATION WITH COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The 1936 House of Delegates instructed "The Council on Medical Education and Hospitals together with the Judicial Council to formulate a plan whereby all those associated in the delivery of medical service be included in the investigation of hospitals for classification and that approval be based in the future on ethical practices in the institution as well as its scientific work." Consequently the Judicial Council met with the Council on Medical Education and Hospitals in February this year and after thorough discussion presented the basis of a plan for the desired cooperation of the two councils. The problem, which involves many difficulties, will require some time for its solution.

VOTING RIGHTS

The Judicial Council desires to bring to the attention of the House of Delegates the practice of constituent associations whereby officers and council members become *ex officio* or active members of the house of delegates with the right to vote. The house of delegates is the legislative body of each association and in many the council is the executive body acting for the house of delegates between annual sessions. The state society council reports its interim activities to the state society house of delegates for approval at the annual session. It seems incongruous for members of the council to act during the year, report their activities to the house, and then seated as delegates vote in judgment on their own previous actions. State society officers and council members should sit with the house of delegates, but the Judicial Council questions the propriety of their recognition as voting members. Perhaps no great harm ordinarily is done, but if the council is numerically large in proportion to the number of elected delegates its members might dominate the house and interfere with action desired by the membership at large. The Judicial Council has reason to believe that such misrepresentation has occurred. In bringing such situations to the attention of the House of Delegates it is the hope of the Judicial Council that corrective action may be taken by constituent associations.

TIME LIMIT ON APPEALS

During the past year the Judicial Council has tried and rendered decisions in four cases appealed to it from decisions of state associations. Two appeals were sustained and two were denied. A fifth appeal was denied a hearing because of refusal on the part of the appellant to comply with the procedure provided in the county society by-laws. It is the experience of the Council that as a rule state society by-laws place no limit on the time within which appeals must be made from decisions of county societies. The By-Laws of this association set no limit. As a consequence, some appeals come to the Judicial Council as long as two or three years after the first decision is rendered, when the production of evidence has become very uncertain and often very difficult. The Council doubtless has power to make rules governing its own procedure but believes it to be proper and advisable to incorporate in the By-Laws a definite limit within which appeal to the Judicial Council from decisions of constituent associations must be made. An amendment will be offered providing for a six months limit.

AMENDMENTS

At the 1936 session, certain amendments to the By-Laws recommended to the House were approved by the proper reference committees but through an oversight were not formally

adopted by the House. These amendments will be presented for formal action during this session.

The Constitution and By-Laws are in confusion with respect to the election of the President-Elect. Article 6, section 1, names the general officers, including the President and President-Elect. Section 2 of the same article provides that these officers be elected annually. The fact is we do not elect a President but do elect a President-Elect, who becomes President one year later at the time of his installation. The By-Laws, chapter IV, section 8, providing for the installation of the President, also refer to "the annual session following that at which he was elected." The Constitution and By-Laws should be changed to conform to the practice which the House of Delegates has followed for more than ten years, and proposed amendments to effectuate such changes will be offered at the proper time. The amendment to the Constitution cannot be accomplished until the 1938 session but there appears to be no reason why the amendment to the By-Laws cannot be made at the present session, as it will only follow the procedure which has been customary in the past and has not heretofore been called into question.

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association:

1. The first phase of the survey of Medical Education in the United States and Canada, authorized by the Board of Trustees in February 1934, has been successfully completed. Eighty-nine institutions have filed reports and have been visited by the Council's representative in company with another member of the Council, the Association of American Medical Colleges or the Federation of State Medical Boards. Three medical schools and the Associated Colleges of Osteopathy declined to report or to permit an inspection by the Council.

In response to the urgent requests of many of the schools surveyed, the Council is preparing confidential reports in graphic form which will be presented to each school as soon as completed, probably by the time of the Atlantic City session. From these pattern maps, officers of an institution may learn where their school stands in relation to other schools with respect to about 100 items used as a basis for comparison.

The survey has revealed certain weaknesses in the organization and administration of a number of schools. Where unsatisfactory conditions have been found, a warning has been given that improvement must be made within a limited time if the Council's approval is to be continued. The stimulating effect of such counsel is already noticeable. Many of the schools, however, will need to be revisited within the next two years in order to learn just how much is being accomplished.

2. In the United States there are ten schools which offer only the first two years of the medical curriculum. For the most part these schools are located in smaller communities where clinical material is so scarce that satisfactory teaching of clinical medicine would be utterly impossible. In many instances, facilities do not exist for the satisfactory teaching of such subjects as physical diagnosis and gross pathology, which involve the use of clinical material. The same is true of the introductory courses in medicine and surgery, which commonly form a part of the second year schedule. Prolonged study of the problem thus presented has led to the adoption of the following policy:

SCHOOLS OF THE MEDICAL SCIENCES

Following the recent survey of the medical schools it was decided that, effective July 1, 1939, the Council will publish a list of schools which teach acceptably gross and microscopic anatomy, biochemistry, physiology, pharmacology, bacteriology and pathology, even though they do not offer a full course leading to a medical degree.

The acceptance of courses involving the use of clinical material shall be left to the discretion of the faculties which admit to advanced standing students transferring from approved schools of the medical sciences.

Surveys of the clinical courses and facilities will be made by the Council and reported to the individual medical schools on request.

3. There remain in this country five unapproved medical schools. One of these admitted no new students last fall and has declared its intention to close as soon as the students now enrolled can be graduated, presumably in 1939.

4. This year, again, the Annual Census of Hospitals met with a response from more than 96 per cent of all registered hospitals and this response represented around 99 per cent of the entire bed capacity. All other agencies, including the census and other departments of the federal government, have failed to get any better than a 70 per cent response. This loyalty on the part of hospitals to the American Medical Association places the Association in a unique position to do for hospitals things which other agencies are not in position to do.

On March 27, 1937, there were 6,189 hospitals, and of these 939 were approved for internships and residencies. These approved hospitals admitted more patients than all the remaining 5,250 hospitals; thus, more than half of all hospital patients are in institutions approved for the formal training of physicians. The remaining 5,250 hospitals are registered but not approved for intern and residency training. One thousand, six hundred and thirty-eight of these are approved as meeting the minimum standards of the American College of Surgeons and have been inspected by the college. This leaves 3,612 hospitals not approved by the College of Surgeons or the Council. No other agency has inspected them. It is safe to assume that little help is given them toward maintaining standards, outside of the publication and distribution of the "Essentials of a Registered Hospital" and the information gleaned at hospital conventions. The Council's staff, in addition to the 939 approved hospitals, some 200 schools for laboratory technicians, thirty-five schools for physical therapy technicians and the schools for occupational therapists, has managed in the last two or three years to see 600 of these smaller hospitals. Even so, there remain over 3,000 hospitals in "no man's land" so far as inspection and regulation by some national authority is concerned.

As a result of the recent census of hospitals, the Council was able to publish in the Hospital Number of THE JOURNAL the approximate extent of overcrowding in the state mental hospitals. Figures covering 247 of these institutions show that only ninety-three were reported free from overcrowding. The excess of the average number of patients over the rated capacity was less than 15 per cent in sixty-one of these hospitals, from 15 to 30 per cent in forty-six, from 30 to 50 per cent in twenty-four and over 50 per cent in four. In states where more adequate facilities have been provided, a higher discharge rate and a larger number of paroles have resulted.

On the other hand, general hospitals are shown to have been overbuilt. Not only is the average occupancy low, but in some general institutions there are whole buildings, parts of buildings, or floors that have never been utilized. This condition suggests that it would be wise for physicians to investigate carefully before lending their support to campaigns for additional hospital facilities.

5. The Council has also received invaluable assistance from the officials of county and state medical societies in the investigation of hospitals beyond the reach of our inspections. The Council is seeking to make still more helpful this cooperation with constituent societies. The Council has found it of mutual advantage to work with certain departments of the federal government, particularly the United States Public Health Service, the Bureau of the Census, the Department of the Interior, and the Children's Bureau. Such activities extend the usefulness of the Council and gains for the Association some measure of friendly interest and appreciation.

The services of 10,000 interns and residents were examined and prepared for recording in the biographic file.

Around 450 cases of apparent broken internship and residency contracts were investigated.

Due to the activities of the Council, the percentage of autopsies performed in hospitals approved for intern training has steadily increased. In 1926, 249 hospitals reported more than 15 per cent autopsies; 329 less than 15 per cent. Correspond-

ing figures for 1935 were: 692 hospitals reported more than 15 per cent autopsies; eleven less than 15. The number reporting better than 30 per cent during the same period increased from 103 to 355.

6. In cooperation with the Judicial Council, efforts are being made to secure information concerning the tendency of some hospitals to engage in the practice of medicine through the device of hiring physicians to care for patients while the hospital itself collects the fee for the services rendered.

7. At the Milwaukee session the Council was authorized to approve such special examining boards as conform to the standards formulated by the Council. The following boards have been so approved:

American Board of Dermatology and Syphilology.
American Board of Internal Medicine.
American Board of Obstetrics and Gynecology.
American Board of Orthopaedic Surgery.
American Board of Pediatrics.
American Board of Psychiatry and Neurology.
American Board of Radiology.
American Board of Urology.

8. The annual review of medical education was published in THE JOURNAL, Aug. 29, 1936.

The list of "Approved Colleges of Arts and Sciences and Junior Colleges" was revised and reprinted in January 1937.

The Pathology Number of THE JOURNAL, Oct. 24, 1936, contained along with other material a list of approved pathologists.

The Hospital Number of THE JOURNAL, March 27, 1937, contained an unusually complete summary of existing conditions in hospitals throughout the United States.

The State Board Number of THE JOURNAL, April 24, 1937, contained information concerning the number of physicians licensed after examination and by endorsement, the number who represent actual additions to the profession, the number of unapproved graduates and foreigners licensed with or without examination, and the latest information concerning state medical licensure and endorsement, and the examinations of the National Board of Medical Examiners and the basic science boards.

At the Annual Congress on Medical Education and Licensure, Feb. 15 and 16, 1937, Dr. Ray Lyman Wilbur, in his chairman's address, cogently presented the fundamental reasons for the position of leadership assumed by the American Medical Association in the field of medical education. At the same time Dr. Herman G. Weiskotten, who has been engaged in the survey of medical schools, gave a most instructive summary of his impressions.

9. Because of the establishment of examining boards in radiology and pathology, the Council will discontinue the maintenance and publication of its lists of physicians specializing in these branches.

10. The Council is now planning a study of graduate medical education in the United States. This will include the systematic courses offered in schools, hospital residencies and other types of apprenticeship, continuation courses for those in practice and the educational programs of medical societies. To carry out this program and at the same time discharge existing responsibilities will require an increase in the Council's staff, provision for which has already been made by the Board of Trustees.

11. The Council is contributing a certain amount of material for the anesthesia exhibit which is being prepared under the direction of the Committee on Scientific Exhibit.

Respectfully submitted.

REPORT OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

To the Members of the House of Delegates of the American Medical Association:

The Council on Scientific Assembly held its usual official meetings during the year and has given consideration to such matters as have been brought to its attention.

The regular annual Conference of Section Secretaries with the Council was held in Chicago Dec. 4, 1936, for the purpose of planning the scientific program for the Atlantic City session.

The General Scientific Meetings, held on Monday and Tuesday of the week of each annual session for several years past, have attracted greater interest each year, and there has been a general increase in attendance. The program of the General Scientific Meetings will be somewhat different this year in that the session on Tuesday morning will be divided into two sections, one dealing with subjects in the field of general medicine and the other with surgical subjects. In cooperation with the secretary of the Section on Dermatology and Syphilology and of the Section on Preventive and Industrial Medicine and Public Health, the Council has arranged for a symposium on syphilis to be presented as a part of the program of the General Scientific Meetings on the afternoon of Tuesday, June 8.

At the Kansas City session in 1936 the Reference Committee on Sections and Section Work offered a recommendation to the House of Delegates that the By-Laws be so amended as to preclude the participation of an individual Fellow in the discussion of more than one paper at any Scientific Assembly.

Section 13 of chapter XIV of the By-Laws now reads as follows: "A Fellow shall present no more than one paper at any Scientific Assembly." The Council on Scientific Assembly is of the opinion that this provision of the By-Laws is wise if it is made to apply specifically to the actual presentation of papers before the scientific sections but feels that this by-law should not be made to apply to the programs of the General Scientific Meetings, and that it should not debar an individual Fellow from participation in the discussions of an individual paper even though he has himself presented a paper before a section or has contributed to the program of the General Scientific Meetings. Not infrequently, papers dealing with entirely new scientific work are presented as parts of section programs, and the Council on Scientific Assembly is of the opinion that, if the By-Laws should be so amended as to make it impossible for one who is particularly well qualified to discuss an important scientific paper to enter into such discussion because his name has appeared on the program in connection with some other paper, the value of such presentations might be seriously lessened. In a number of instances it has seemed desirable to have as contributors to the program of the General Scientific Meetings Fellows who have accepted places on section programs, because they are thoroughly well qualified to discuss subjects that are of important, immediate interest to the rank and file of the profession. For these reasons particularly, the Council on Scientific Assembly respectfully recommends to the House of Delegates that the proposed amendment to the By-Laws submitted at the Kansas City session be not adopted.

The official program of the Atlantic City session is submitted as a part of the report of the Council.

Respectfully submitted.

SATURDAY, MAY 1, 1937

OBITUARIES OF PHYSICIANS PUBLISHED IN 1936

A total of 3,581 obituaries of physicians was published in THE JOURNAL during 1936 including 3,475 of the United States, as compared with 3,319 in 1935. The number includes also 106 Canadians, 3 who died in the Philippine Islands, 2 each in Africa, Alaska, England, India and South America, and 1 each in China, Costa Rica, Hawaii, Panama and Puerto Rico. The obituaries of 103 women physicians were published, as compared with 83 in 1935. The number of graduates of medical schools in the United States for the fiscal year ended June 30, 1936, was 5,183. Therefore the net increase in the medical profession is 1,708.

Ages.—The average age at death of those classified as of the United States was 64.5, as compared with 64.2 in 1935. Thirty-six physicians died between the ages of 25 and 29, 65 between 30 and 34, 69 between 35 and 39, 80 between 40 and 44, 190 between 45 and 49, 262 between 50 and 54, 423 between 55 and 59, 525 between 60 and 64, 512 between 65 and 69, 460 between 70 and 74, 424 between 75 and 79, 254 between 80 and 84, 115 between 85 and 90, and 49 between 90 and 95; 10 were more than 95.

Causes of Death.—Heart disease was again the leading cause of death, as for the last several years. Some contributory causes are included. For example, when a report of the cause of death gave "chronic nephritis and heart disease," it was published as such in THE JOURNAL and was recorded on the statistical charts under both diseases. Of the causes of death from heart disease, endocarditis or myocarditis was specified in 404 cases, coronary thrombosis in 213, angina pectoris in 105 and pericarditis in 1. Other diseases of the heart caused 652 deaths. Pneumonia was the second most frequent cause with 426 deaths, of which 110 were specified as bronchopneumonia. Cerebral hemorrhage was the third most frequent cause, with 367 deaths; 21 additional deaths were reported as due to paralysis. Fourth on the list was arteriosclerosis, with 352 deaths. Of 306 deaths reported as due to cancer, the stomach and liver were affected in 68 cases.

the prostate in 52, the intestine in 23, the female genital organs in 1, the buccal cavity in 1; in 160 cases the part affected was not specified. Nephritis caused 206 deaths, of which 18 were specified as acute nephritis. The number of cases in which embolism or thrombosis exclusive of coronary thrombosis was reported was 106, hypertension 87, diabetes mellitus 79, uremia 73, other diseases of the genito-urinary system 73, tuberculosis of the respiratory system 58, other forms of tuberculosis 3, cirrhosis of the liver 42, diseases of the prostate 40, senility 36, influenza 31, appendicitis 30, ulcer of the stomach and duodenum 28, intestinal obstruction 26, septicemia 24, hemorrhage and paralysis agitans 22 each, peritonitis 21, leukemia 16, meningitis 15, arthritis 14, diseases of the digestive system 14, cholecystitis 13, erysipelas 11, asthma 10, biliary calculi and brain tumor 9 each, aneurysm and pernicious anemia 8 each, gangrene 7, agranulocytosis, bronchitis, heat prostration and mastoiditis 6 each, cellulitis, diverticulitis, encephalitis, hernia, Hodgkin's disease, diseases of the liver and streptococcal infection 5 each, pancreatitis, scarlet fever, sinus infection and other diseases of the respiratory system 4 each, acute articular rheumatism, alcoholism, benign tumor, diseases of the veins, emphysema, empyema, multiple sclerosis, osteomyelitis, dementia paralytica and streptococcal sore throat 3 each, and Addison's disease, bacillary dysentery, carbuncle, malaria, multiple neuritis, otitis media, pleurisy and softening of the brain 2 each. Among other causes of death, each given in one case, were amebic dysentery, amyloidosis, brain abscess, cerebral atrophy, cerebral infarct, cerebral sclerosis, diphtheria, disseminated sclerosis, furunculosis, glaucoma, infection of the tongue, intestinal ulcer, Malta fever, multiple myeloma, osteitis fibrosa, Paget's disease, paralytic ileus, pellagra, pharyngitis, poliomyelitis, regional ileitis, ruptured coronary artery, ruptured gallbladder, scurvy, splenic infarction, splenomegaly, stricture of the esophagus, sunstroke, thrombo-angiitis obliterans, tonsillitis, traumatic epilepsy, typhoid, typhus, and Vincent's angina.

Accidental Deaths.—One hundred and eighty-two physicians died as the result of accidents in 1936, compared with 120 in the previous year. Automobile accidents accounted for 86 deaths, 15 more than in 1935. In 1936, deaths from falls numbered 37, drowning 9, injuries received in diving 2, shooting 8, overdoses of medicine 7, burns 6, carbon monoxide gas and train accidents 3 each, airplane accidents 2, and poisoning, street car accident, gas and overdose of anesthetic 1 each. In several cases unexplained fractures were given as causes of death. One was killed in Ethiopia in a bomb explosion, one was suffocated in a fire, and one was electrocuted by contact with the wires to an x-ray machine. One died as the result of the injury received when his lungs were pierced by surgical scissors in a fall.

Suicides and Homicides.—Suicide was the cause of 59 deaths in 1936, 12 more than in 1935. Shooting

accounted for 30 of these deaths, hanging and poisoning 5 each, carbon monoxide poisoning and incised artery 4 each, overdoses of morphine, jumping and scalpel wounds 2 each, chloroform and drowning 1 each. In the remaining cases the method was not mentioned. There were 4 homicides.

Civil Positions.—Among the decedents were 235 who were or had been teachers in medical schools, 426 who served in the World War, 27 veterans of the Civil War and 52 veterans of the Spanish-American War. One hundred and fifty-nine were or had been health officers, 119 members of boards of education, 98 members of boards of health and 20 members of state boards of medical examiners. There were 61 coroners, 50 mayors, 46 members of state legislatures, 27 authors, 26 bank presidents, 22 members of city councils, 22 pharmacists, 15 medical missionaries, 12 postmasters, 8 dentists, 8 editors, 7 clergymen, 4 police surgeons, 2 justices of the peace and 1 judge. There were 17 members of the U. S. Army Medical Corps, 13 of the U. S. Navy Medical Corps, 15 of the U. S. Public Health Service, 6 of the U. S. Veterans' Administration and 2 of the Indian Medical Service.

Association Officers.—Obituaries of physicians who were or had been officers of the American Medical Association included the obituary of Dr. James Tate Mason, who was President at the time of his death, 1 past president, 3 vice presidents, 2 former trustees, 15 section officers and 4 members of councils. Thirty-two members or former members of the House of Delegates died during the year. Thirty-four presidents or former presidents and 10 secretaries of the state societies were included among the officials.

FEDERAL REGULATION OF MEDICINAL USE OF CANNABIS

The Secretary of the Treasury has procured the introduction in the House of Representatives of a bill, H. R. 6385, imposing an occupational excise tax on certain dealers in cannabis, a transfer tax on certain dealings in cannabis, and providing for safeguarding the revenue therefrom by registry and recording. The primary purpose of the bill is to regulate and control the production and use of cannabis by federal authority, in order to prevent cannabis addiction. It is proposed to resort to the federal taxing power, as was done in the enactment of the Harrison Narcotic Act, and then, under regulations that in theory are necessary for the collection of the tax, to control the production, manufacture and use of cannabis and its compounds and derivatives for all purposes whatever. The persons whom it is proposed to tax and the rates of taxation are:

Physicians, dentists, veterinary surgeons and other practitioners, \$1 a year or fraction thereof.

Teachers, analysts and research workers who use cannabis or its compounds or derivatives in laboratories, \$1 a year or fraction thereof.

Wholesale and retail druggists and others who are not physicians, dentists, veterinary surgeons or other practitioners, nor importers, manufacturers, compounders or producers, \$15 a year.

Importers, manufacturers and compounders, \$50 a year.

Producers, \$25 a year.

These taxes are to be payable without regard to the payment of analogous taxes under the Harrison Narcotic Act. They will probably amount to upward of a million dollars a year.

Certainly cannabis addiction cannot be traced to the medicinal use of cannabis. The medical profession today seldom dispenses or prescribes the drug. Many physicians will, however, probably feel it necessary to preserve their right to use it if and when circumstances make it advisable to do so and accordingly will feel compelled to pay the tax. Pharmacists presumably seldom have calls for cannabis, but they must nevertheless be prepared to dispense it when a call does come, so they will have to pay the tax. For the same reason the wholesale druggist and many manufacturers of drugs will feel compelled to pay. The million dollars to be collected annually by the federal government will no doubt be charged as a part of the cost of practicing medicine, dentistry and pharmacy. So also will the expense of record keeping and reporting, called for under the bill. All this will in the end be paid for by the patient and thus go to swell the cost of sickness. Thus the sick and injured must contribute toward federal efforts to suppress a habit that has little or no relation to the use of cannabis for medicinal purposes and that is already within the jurisdiction of the several states.

Without resorting to taxation, the federal government has complete authority over cannabis and its compounds and derivatives in interstate and foreign commerce and in the mails. It can control them in the territories and the District of Columbia and in other places under the exclusive jurisdiction of the federal government. It can give every state complete control over cannabis and its compounds and derivatives the moment they cross the state boundary, to supplement authority constitutionally vested in the state. Forty-six states and the District of Columbia already have laws relating to such drugs. If these laws are not adequate, or if they are not adequately enforced, the Secretary of the Treasury is under a statutory duty to cooperate with the states that are inadequately policed, to bring about the necessary improvement in the situation.

The proposed federal venture into the intrastate control of cannabis hardly seems to be justified by experience under the Harrison Narcotic Act. After more than twenty years of federal effort and the expenditure of millions of dollars, the opium and cocaine habits are still widespread. The best efforts of an efficient bureau of narcotics, supplemented by the efforts of an equally efficient bureau of customs, have failed to stop the unlawful flow of opium and coca leaves and their compounds and derivatives, on which the continuance and spread of narcotic addiction depends. The best efforts

of the Public Health Service to find means for the prevention and cure of narcotic addiction have not yet accomplished that end. Two federal narcotic farms, operating under the supervision and control of the U. S. Public Health Service, cannot yet guarantee the cure of narcotic addiction. What reason is there, then, for believing that any better results can be obtained by direct federal effort to suppress a habit arising out of the misuse of such a drug as cannabis? Certainly it is almost as easy to smuggle into the country and to distribute as are opium and coca leaves. Moreover, it can be cultivated in many parts of the United States and grows wild in field and forest and along the highways in many places.

All rights that the government aims to obtain under the pending bill, at a cost of upward of a million dollars annually, can be obtained just as well and without levying any such taxes as are now proposed, by amendments to the Harrison Narcotic Act! Unless the bill has implications that have not yet been discovered, there is no reason why they should not yet be so obtained, if they are to be granted at all. The proposed levying of an additional tax on the agencies engaged in the treatment of the sick is definitely unwarranted.

CAUSATIVE FACTORS IN ERYTHEMA NODOSUM

Erythema nodosum, dermatitis contusiformis, or nodular fever of Lendon, named by the French physician Robert Willan in 1799, has been generally considered in continental Europe to be of tuberculous origin. In England and in this country it has also been found to be associated with streptococcic sore throat, acute endocarditis, influenza, measles, chickenpox, ulcerative colitis, lymphogranuloma venereum, gonococcic septicemia, abscesses about the roots of the teeth, and following the ingestion of iodides. Many consider the condition a specific acute infectious disease. Moon and Strauss¹ described an organism of the genus *Corynebacterium* which they thought responsible for the disorder. Rosenow described a diphtheroid organism which he isolated from several patients and which the Philadelphia workers thought might be identical with their own.

Spink² recently studied ten patients with erythema nodosum and reported on 133 patients treated at the Boston City Hospital. Skin lesions were excised from patients with the disease and from patients who had been given intradermal injections of streptococcus endotoxin (nucleoprotein) and of tuberculin. Practically the same histologic changes were found in all, so that as far as etiology goes it seems that not much help is to be derived from microscopic study of the lesions. In this study there seemed to be a close association of the

eruption with streptococcic infections, but other factors also were involved. Five of the ten patients had a sore throat prior to the onset; two had painful joints. Throat cultures in four patients revealed *Streptococcus haemolyticus* of the beta type, and eight of the patients gave a positive skin reaction to an intradermal injection of the streptococcus nucleoprotein fraction. Of the 133 patients observed from 1924 to 1934, of whom 111 were females, the eruption appeared to have a seasonal incidence closely paralleling that of the acute streptococcic infections such as acute follicular tonsillitis, scarlet fever and erysipelas. It also followed exposure to streptococcic infection. Rheumatic heart disease was present in 11.2 per cent of the patients; one had acute mitral disease and chorea. In only two cases was there a history of exposure to tuberculosis.

Tuberculosis, however, as a causative factor, has been observed too frequently to be disregarded. Especially in children does it appear to have a definite relationship. Scandinavian observers have noted that erythema nodosum is almost as frequent a complication of tuberculosis as pleurisy, and children who develop the disease are presumed to have tuberculosis until proved otherwise. The tuberculin reaction is often negative before the lesions appear but becomes positive when they do, or shortly after. Phlyctenular conjunctivitis is often associated.

The authors conclude that the disease, if such it may be called, is a nonspecific inflammatory reaction due to a variety of bacterial, toxic and chemical agents. The etiologic factor is usually of a streptococcic or tuberculous nature, the latter more commonly in children. Other causes are not infrequent and must be looked for and eradicated when possible.

RECENT REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry has issued a number of reports during the last few months indicative of its constant efforts to keep abreast of the newest therapeutic advances. The description of protamine zinc insulin, together with its actions and uses, was elaborated by the Council (*THE JOURNAL*, February 20, p. 640) in close cooperation with representatives of the Insulin Committee of the University of Toronto. The Council's report gives succinctly the essential attributes of the preparation.

Ingestion of the nonmetabolizable substance called mandelic acid imparts to the urine a sufficient degree of acidity to yield effective bactericidal action provided certain pathologic conditions are not present. The Council's report on this product (*THE JOURNAL*, March 27, p. 1033), prepared for the Council by Dr. William F. Braasch, informed the profession of the essential properties of mandelic acid therapy. However, the Council, with admirable caution, decided that the time was not yet ripe to accept the product for inclusion in *New and Nonofficial Remedies* and voted to await fur-

1. Moon, V. H., and Strauss, Abram: Erythema Nodosum, *Arch. Dermat. & Syph.* 26:78 (July) 1932.

2. Spink, W. W.: Pathogenesis of Erythema Nodosum, *Arch. Int. Med.* 59:65 (Jan.) 1937.

ther evidence concerning the harmlessness and usefulness of the drug. The Council felt that there are as yet insufficient pharmacologic data. As has been brought out in other papers in *THE JOURNAL*, if mandelic acid is not used properly and at times under careful institutional control, untoward results may follow. A number of physicians have written to *THE JOURNAL* concerning toxic reactions. Dr. Braasch emphasizes the need of determining whether or not primary renal insufficiency exists before the drug is employed.

Surgeons, particularly, should be interested in the report on the status of catgut sutures (*THE JOURNAL*, February 27, p. 722) prepared under the direction of the Council on Pharmacy and Chemistry at the request of the Board of Trustees. The survey was undertaken with two objects in view: first, to study critically the technic that has been employed heretofore in testing the sterility of catgut sutures, to modify this technic as might seem desirable and to describe it in such a manner that it might be of use to manufacturers of sutures and others interested in the control of these products; and, second, to determine the status of sterility of sutures now available on the American market and especially of those recently manufactured in comparison with those on the market some years ago. Of fourteen brands tested, samples of six firms were found not sterile. Four of the fourteen firms no longer manufacture sutures. If only sutures of recent manufacture are considered, the percentage of firms placing nonsterile products on the market drops from 43 to 12.5, indicating a decided improvement. In view of this work the Council issued a warning against the use of so-called chemically sterilized sutures; in the opinion of the Council it is better to use only heat sterilized sutures until more reliable chemical processes have been devised. The Council also felt that manufacturers should place on their labels a date of manufacture and that physicians should use those sutures which bear a date more recent than Oct. 8, 1936, at which time the report was submitted to the manufacturers. It may be stated that in the case of some of the manufacturers immediate steps were taken to safeguard further their supply of sutures. Indeed, one large manufacturer has entirely discarded his old plant and installed new machinery and a new technic. Because of the interest in this report there has been recently introduced in Congress by Senator David I. Walsh of Massachusetts a bill to place the control of ligatures under the U. S. Public Health Service. Undoubtedly physicians would approve any further safeguards that might be offered. In the meantime, the Board of Trustees and the Council on Pharmacy and Chemistry have arranged for a further survey of the market supply of catgut sutures.

In another recent issue of *THE JOURNAL* (April 3, p. 1172) appeared a comprehensive report on Evipal Soluble (Evipan Sodium), a quick acting hypnotic of the barbituric acid series. The Council voted that the drug be declared unacceptable until more trust-

worthy methods are available for determining the safe and effective dosage under a wide variety of conditions, until the contraindications—both relative and absolute—have been adequately determined, and until comprehensive pharmacologic studies make possible the fixing of responsibility of the anesthetic in many of the available clinical reports of accidents. The Council has repeatedly warned the profession concerning the dangers of the intravenous use of nonvolatile anesthetics except in case of emergencies; it recognizes and accepts products which are recommended for use as basal anesthetics.¹ In the case of Evipal Soluble the Council has analyzed a series of deaths arising from the injection of this barbital derivative. The Council recognizes that Evipal Soluble may have a restricted field of usefulness in which it may be employed with relative safety provided it is used with skill and with due regard for its limitations.

The work here reported is another tribute to the value of the American Medical Association. Only such an organization could provide the funds to maintain an unbiased body which reports fearlessly and with authority on preparations which doctors are importuned to use. Such work is costly both in time and in money. Members of the Council receive no remuneration for their work and contribute time taken from busy professional careers. The laboratory, personnel and facilities of the Council have recently been described in the Organization Section of *THE JOURNAL*. The profession will undoubtedly be interested in forthcoming reports of the Council, which will deal with further problems of current medical interest.

Current Comment

SCIATIC PAIN AND ITS RELIEF

Freiberg¹ has recently reported several important observations on the anatomic relations of the sciatic nerve. The piriformis muscle, he states, is constantly found to have a part of its origin from the capsule of the sacro-iliac joint, and it is the only muscle which bridges that joint. This muscle is in extremely close relationship with the sciatic nerve. The nerve, in fact, is found to penetrate the substance of the muscle in 10 per cent or more of cadavers. Experiments on cadavers show that by the Lasègue maneuver the piriformis is put on the stretch after only a few degrees of straight leg raising through the medium of the biceps femoris muscle and its connection with the great sciatic ligament, from which the piriformis derives a part of its origin. The piriformis may therefore be expected to react by spasm as the result of disease in the sacro-iliac joint because of its partial derivation from the capsular ligament of this joint. It follows that the possibility of direct involvement of the sciatic nerve must be granted in case of disease or spasm of the piriformis.

1. Intravenous Use of Barbitol Compounds, Reports I and II; *THE JOURNAL*, Dec. 19, 1931, p. 1886, and July 15, 1933, p. 208.

1. Freiberg, A. H.: Sciatic Pain and Its Relief by Operations on Muscle and Fascia, *Arch. Surg.* 34: 337 (Feb.) 1937.

These observations led Freiberg to the belief that the relationship of the piriformis muscle to the sciatic nerve might be of practical importance. In demonstration of this he cites two cases of sciatic pain attributed to the piriformis muscle in which relief was obtained by cutting the iliotibial band when in contraction or by section of the piriformis muscle in the absence of the Ober sign of abduction contracture. Obviously, however, this operation for relief, when indicated, cannot be considered to fulfil the responsibility demanded by sciatic pain. Nevertheless, according to Freiberg it seems justifiable that by means of these relatively simple and safe procedures new hope can be offered to a group of cases heretofore highly refractory to professional intervention. As such a measure, Freiberg's proposal seems to offer a subject worthy of further investigation.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

State Medical Meeting and Election.—Dr. Harold W. Rice, Bisbee, was chosen president-elect of the Arizona State Medical Association at its annual meeting in Yuma, April 1-3, and Dr. Chester R. Swackhamer, Superior, was installed as president. Other officers are Drs. William Paul Holbrook, Tucson, vice president; Clarence E. Yount, Prescott, treasurer, and Delamere F. Harbridge, Phoenix, secretary. A public meeting was held Wednesday evening, March 31, with Dr. William W. Bauer, director, Bureau of Health and Public Instruction, American Medical Association, Chicago, as the principal speaker; his subject was "Health for Today." Dr. Bauer also addressed the state association Friday afternoon on "Doctors as Health Teachers." Other guest speakers included:

- Dr. Norman N. Epstein, San Francisco, Artificial Fever Therapy.
- Dr. Henry Dietrich, Los Angeles, Fallacies in the Care and Treatment of Children.
- Dr. John C. Wilson, Los Angeles, Present Status of Treatment of Fractures of the Neck of the Femur.

Greetings from the Texas and New Mexico state medical associations were presented by Drs. Robert B. Homan, El Paso, and Fred D. Vickers, Deming, N. M., respectively. In addition to many other Arizona physicians on the program, the following participated in a session on industrial relations:

- Dr. Jesse D. Hamer, Phoenix, Report of the Industrial Relations Committee.
- Dr. Ralph F. Palmer, Phoenix, Industrial Surgery in Arizona; Responsibility of Organized Medicine and the Individual Industrial Surgeon Thereof.
- Drs. Emile C. Houle, Nogales, and Charles P. Austin, Douglas, Traumatic Emergency Surgery.
- Dr. William Jewell Smith, Phoenix, Injuries to the Eye Resulting from Foreign Bodies.
- Mr. Carl Holmes, The Arizona State Industrial Commission.

The woman's auxiliary held its annual meeting, April 1-2. The speakers were Mrs. James F. Percy, Los Angeles, Mrs. Philip S. Doane, Pasadena, and Mrs. Mark A. Glaser, Los Angeles.

CALIFORNIA

Society News.—Dr. Claude W. Munger, formerly of Valhalla, N. Y., now of New York, addressed the Hollywood Academy of Medicine, April 15, on "The Internship—An Opportunity in Medical Education."—Dr. Bransford Lewis, St. Louis, addressed the Los Angeles County Medical Association, March 18, on "Nephropexy, the Neglected Stepchild of Surgery."—At a joint meeting of the Los Angeles Society of Ophthalmology and Otolaryngology and the Research Study Club of Los Angeles, April 26, the speakers were Drs. Grant L. Selfridge, San Francisco, on "Chronic Progressive Deafness from a Nutritional Standpoint" and Walter P. Covell, San Francisco, "Experimental Nerve Deafness from the Standpoint of Drugs, Toxins and Dietary Factors."

DISTRICT OF COLUMBIA

Annual Scientific Assembly, May 5-6.—The annual scientific assembly of the Medical Society of the District of Columbia will be held, May 5-6, under the presidency of Dr. William Mercer Sprigg. A complimentary luncheon will be given at the Mayflower Hotel, Wednesday, with Arthur Deerin Call, Ph.D., editor of *World Affairs*, Washington, as the guest speaker; his subject will be "As to the Prospects for War." A public meeting Wednesday evening will be addressed by Dr. Howard Wilcox Haggard, New Haven, Conn., on "Medicine and the Public." Guest speakers will include Drs. Francis G. Blake, Sterling professor of medicine, Yale University School of Medicine, New Haven, on "Serum Therapy in Pneumonia," and James C. White, assistant professor in surgery, Harvard University Medical School, Boston, on "The Sympathetic Nervous System in Relation to Cardiovascular Disease." Other speakers will include:

- Dr. Howard P. Parker, Paraldehyde-Benzyl Alcohol Obstetrical Analgesia by the Kane-Roth Method.
- Dr. Agnes B. W. Greig, Learning Disability in Intelligent Children—A Symptom of Emotional Disturbance.
- Dr. Arthur C. Christie, The Socialization of Medicine: To What Extent Is It Desirable?
- Dr. Henry B. Gwynn, Artificial Fever Therapy of Gonorrheal Arthritis.
- Drs. Walter Freeman and James W. Watts, The Surgical Treatment of Mental Disorders.
- Dr. John H. McLeod, The Use of Acacia in the Relief of Edema in Lipoid Nephrosis.
- Dr. Harry A. Fowler, Mandelic Acid: The New Urinary Antiseptic.

A tour of the crime laboratory of the federal bureau of investigation will be a feature of the meeting, and trips are planned to the Smithsonian Institution and the National Institute of Health. Clinics are scheduled for Thursday morning, and, in the evening, the annual banquet at the Mayflower Hotel. The woman's auxiliary will also hold its annual session during the two days.

GEORGIA

State Medical Meeting at Macon, May 11-14.—The eighty-eighth annual session of the Medical Association of Georgia will be held at the Municipal Auditorium, Macon, May 11-14, under the presidency of Dr. Benjamin H. Minchew, Waycross. Dr. Minchew will give his official address Thursday, entitled "The Responsibility of the Layman in a Public Health Program." The Abner Wellborn Calhoun Lecture will be delivered Wednesday by Dr. Isaac A. Abt, professor of pediatrics, Northwestern University Medical School, Chicago, on "The Story of the Vitamins in Infant Nutrition." Other guest speakers will include:

- Dr. John H. J. Upham, Columbus, Ohio, President-Elect, American Medical Association, Heart Disease in Middle Life.
- Dr. Roy D. McClure, Detroit, The Control of Thyroid Disease in Michigan.
- Dr. Charles Franklin Craig, professor of tropical medicine, Tulane University of Louisiana School of Medicine, New Orleans, Tropical Diseases of Interest to Southern Physicians.
- Dr. Olin West, Secretary and General Manager, American Medical Association, Chicago.

In addition to the presentations by Georgia physicians, the program will include symposiums on fractures and on tuberculosis.

IDAHO

Dr. Dunshee Appointed Director of Public Health.—Dr. Jay D. Dunshee, public health adviser in the Department of Public Welfare of Idaho, Boise, has been appointed director of the division of public health, created in the department March 6 by the state legislature. A division of charitable institutions was also created, but up to April 1 no director of institutions had been appointed. Dr. Dunshee graduated from the State University of Iowa College of Medicine, Iowa City, in 1908. He engaged in private practice from 1908 to 1917 and from 1921 to 1926 was director of child welfare in Los Angeles. He served as health officer of Pasadena from 1929 until 1934, when he was appointed director of the state department of health of California. He has been with the Idaho department since 1936.

ILLINOIS

Meeting of Bacteriologists.—The Society of Illinois Bacteriologists will hold its annual meeting Friday evening May 7, in joint session with the Tri-State Hospital Association and affiliated organizations, at the Hotel Sherman, Chicago. The speakers will include:

- L. Enos Day, Chicago, Accomplishments of Veterinary Medicine in Control of Human Tuberculosis.
- G. V. Hallman, M.S., Chicago, Relation of Thermophilic Bacteria to Spoilage of Canned Foods.
- Dr. Alfred S. Giordano, South Bend, Ind., Diagnosis of Undulant Fever.
- Dr. Emil Weiss, Chicago, Complement Fixation in the Diagnosis of Amebiasis.

State Department and the Administration of Venereal Disease Clinics.—Numerous applications received by the state department of health from physicians seeking employment as clinicians in venereal disease clinics indicate an erroneous idea concerning the administrative policy with respect to the program of venereal disease control in Illinois, according to an announcement. The state department does not operate and does not propose to establish any clinics for the treatment of patients infected with venereal diseases. The department has begun and proposes to expand the practice of rendering financial aid to local communities for the establishment and operation of venereal disease clinics which are a factor in a community program of social hygiene. The administration of the clinics as well as the entire program is a local matter, the state department of public health insisting only that the personnel engaged be well qualified and the program meet reasonably high standards. Otherwise local authorities will have complete jurisdiction over the employment of personnel and the execution of the work.

Chicago

Society News.—At a meeting of the Chicago Society of Internal Medicine, April 26, the speakers included Drs. Lester R. Dragstedt, John Van Prohaska, Paul B. Donovan, Ph.D., and Dr. William A. Geer on "Lipocais, A New Pancreatic Hormone" and Richard L. Webb, Ph.D., "Mesenteric Lymphatics: Analysis of the Mechanism of Drug Action as Revealed by Motion Pictures."—The Institute of Traumatic Surgery held an all day session at St. Luke's Hospital, April 23; the guest speaker was Dr. Willis C. Campbell, Memphis, Tenn., and his subject, "Ununited Fractures of the Neck of the Femur."—Dr. Albert Bessemans, formerly rector, University of Ghent, Belgium, lectured April 23 under the auspices of Northwestern University Medical School and the Institute of Medicine of Chicago; on "Experimental Data on Antisyphilitic Hyperpyrexia Produced by Physical Agents."

INDIANA

Annual Graduate Course.—The Indiana University School of Medicine and the state medical association will present their annual graduate course at the medical school and the Lincoln Hotel, Indianapolis, May 10-14. Clinics, demonstrations, lectures and clinical pathologic conferences will be offered on the specialties during the day, and evening programs will be presented by the following:

- Dr. Samuel A. Levine, assistant professor of medicine, Harvard University Medical School, Boston, Cardiology.
- Dr. Vernon C. David, clinical professor of surgery, Rush Medical College, Chicago, Surgery.
- Dr. Nicholson J. Eastman, professor of obstetrics, Johns Hopkins University School of Medicine, Baltimore, Obstetrics.
- Dr. Frank C. Mann, professor of pathology, surgery and experimental physiology, University of Minnesota, Graduate School of Medicine, Rochester-Minneapolis, Physiology.
- Dr. Harold N. Cole, associate clinical professor of dermatology and syphilology, Western Reserve University School of Medicine, Cleveland, Syphilis.

A public meeting Friday evening, May 14, will be addressed by Maud Slye, A.B., associate professor of pathology, University of Chicago, on cancer. The first day of the course has been designated "Pediatrics Day," the program to be presented by the Indiana State Pediatric Society.

IOWA

State Medical Meeting at Sioux City, May 12-14.—The eighty-sixth annual session of the Iowa State Medical Society will be held at the Masonic Temple, Sioux City, May 12-14, under the presidency of Dr. Prince E. Sawyer, Sioux City. A symposium on gallbladder disease will be given Wednesday morning by Drs. Ewen M. MacEwen, Fred M. Smith, Carl L. Gillies and Frank R. Peterson, all of Iowa City. Thursday morning the program will be presented by the following:

- Dr. Louis Hamman, Baltimore, Syphilis of the Heart and the Aorta.
- Dr. Dean D. Lewis, Baltimore, Endocrinology as Related to Surgery.
- Dr. Sanford R. Gifford, Chicago, Recent Views of Senile Cataract.
- Dr. Alexis F. Hartmann, St. Louis, Hyperinsulinism and Hypoglycemia in Infants and Children.

Thursday and Friday afternoons have been set apart for sectional conferences, and the following speakers are scheduled for Friday morning:

- Dr. Lewis, Surgical Lesions of the Breast.
- Dr. Hamman, Abdominal Tumors.
- Dr. Charles Gordon Heyd, New York, President, American Medical Association, Medical Economics.

At the smoker Wednesday evening there will be several rounds of boxing. At the banquet at the Hotel Martin, Thursday evening, Dr. Arthur D. Woods, State Center, will be

toastmaster, and the speakers will be Dr. Sawyer, Dr. Edward M. Myers, Boone, president-elect, and Mr. Arthur F. Briese, Chicago. The State Society of Iowa Medical Women and branch 19, Medical Women's National Association, will meet at the Hotel Martin, May 12. The speakers will include Drs. Goldie E. Zimmerman, Sioux Falls, S. D., on "The Value of Medical Supervision During Early Childhood," and Nora Winther, Minneapolis, "Trichomonas." The eighth annual meeting of the woman's auxiliary of the Iowa State Medical Society will be held May 9.

KANSAS

State Medical Meeting at Topeka, May 3-6.—The seventy-eighth annual session of the Kansas Medical Society will be held in the Masonic Temple, Topeka, under the presidency of Dr. Howard L. Snyder, Winfield. The program includes the following speakers:

- Dr. Meyer Wiener, St. Louis, Surgery of Glaucoma.
- Dr. Everett D. Plass, Iowa City, Management of Abortions.
- Dr. James H. Mitchell, Chicago, Streptococcal Dermatoses.
- Dr. Thomas E. Carmody, Denver, Sinus Disease in Children.
- Dr. Claude F. Dixon, Rochester, Minn., Cancer of the Colon.
- Dr. Robert C. Jeffries, Atchison, of Injuries mmon Auto-
- Dr. Earl C. Padgett, Kansas City, mobile Injury.
- Dr. William M. Ketcham, Kansas City, Mo., Hypertensive Heart Disease.
- Dr. Thomas G. Orr, Kansas City, Diagnosis and Treatment of Breast Cancers.
- Dr. Russell L. Haden, Cleveland, Clinical Approach to the Rheumatic Problem.
- Dr. Arnold S. Jackson, Madison, Wis., Regional Enteritis.
- Dr. Archibald L. Hoyne, Chicago, Progress in the Treatment of Meningococcal Meningitis.
- Dr. Elliott P. Joslin, Boston, The Diabetic as a Surgical and an Obstetrical Risk.
- Dr. John Albert Key, St. Louis, Treatment of Elbow and Wrist Fractures.
- Dr. Philip C. Jeans, Iowa City, Recent Advances in Nutrition.
- Dr. Charles F. Taylor, Norton, A Report of Sixty Consecutive Intrapleural Pneumolyses.
- Dr. Christian A. Hellwig, Wichita, Uterine Bleeding After Forty.
- Dr. Herbert J. Rinkel, Kansas City, Mo., Diagnostic Problem in Food Allergy.
- Dr. Walter E. Thornton, Fort Wayne, Ind., Relation of Life Insurance to Medical Practice.

The annual banquet will be held at the Topeka High School followed by a dance on the Hotel Jayhawk Roof. The Kansas branch of the Medical Women's National Association will meet at breakfast Thursday morning. The Kansas Medical Golfing and Trapshooting associations will hold their tournaments Monday; in the evening there will be a joint stag banquet.

KENTUCKY

Mortality in the Recent Flood.—The director of the bureau of vital statistics of the state board of health has reported to the U. S. Public Health Service deaths resulting directly and indirectly from the flood between January 22 and February 28. The figures are: pneumonia 252 (of which 139 were in Louisville), influenza 54, drowning in flood waters 16, explosion 15, exposure 10, accident (other than drowning and explosion) 9, heart disease 7, total 363. The public health service points out that the significance of these figures lies in the small numbers. There was no outbreak of epidemic disease.

MASSACHUSETTS

"Eye Specialist" Birnstein Sentenced Again.—Samuel Birnstein, New Orleans, was fined \$600 and sentenced to two years in the house of correction by Superior Judge Thomas J. Hammond, February 24, for participation in the activities of a ring of fake eye specialists, newspapers reported (THE JOURNAL, Nov. 14, 1936, page 1643). Since Birnstein pleaded guilty last October to a charge of larceny after his arrest by postal inspectors in New Orleans, he has repaid his victims in this charge \$1,500 of the \$2,000 he received from them. The judge announced that he would reduce the fine against Birnstein to a nominal amount if the sum was paid in full during the remaining few weeks of that sitting of the court, it was reported. In January Birnstein was indicted with others by a federal grand jury in Milwaukee, where he pleaded guilty to charges of conspiracy and using the mails to defraud. He was fined \$1,000 and sentenced to two years in federal prison, the sentence to be served on the completion of his term in the house of correction in Massachusetts.

MINNESOTA

Dr. Maxcy Goes to Johns Hopkins.—Dr. Kenneth F. Maxcy, professor and head of the department of preventive medicine and public health, University of Minnesota School of Medicine, Minneapolis, has been appointed professor of bacteri-

ology at Johns Hopkins University School of Hygiene and Public Health, Baltimore, effective July 1. He succeeds Dr. William W. Ford, who has held the position since 1920 and is retiring on account of the age limitation. Dr. Maxcy graduated from Johns Hopkins University School of Medicine in 1915. He resigned as professor of preventive medicine and bacteriology at the University of Virginia School of Medicine, Charlottesville, to accept the position at Minnesota in 1936. Recently he was appointed to a three year term with the International Health Division of the Rockefeller Foundation as one of the scientific directors. Dr. Ford is also a graduate of Johns Hopkins and has been associated with the school in various capacities since 1903.

MISSOURI

State Medical Meeting at Cape Girardeau, May 10-12.—The eightieth annual session of the Missouri State Medical Association will be held at the State Teachers College, Cape Girardeau, May 10-12, under the presidency of Dr. Ross A. Woolsey, St. Louis. Five general meetings and one public meeting will be held, with the maternal welfare committee holding a dinner session at the Marquette Hotel Monday. Dr. Norman F. Miller, professor of obstetrics and gynecology, University of Michigan Medical School, Ann Arbor, among others, will address this dinner meeting on "Critique of Submitted Maternal Death Reports." Dr. Miller will also present a paper entitled "How Bad Is Obstetric Care?" at a general session Tuesday. Dr. Herman E. Pearse Jr., Rochester, N. Y., will speak Wednesday on "Care of Infections of the Neck and Their Complication, Mediastinitis." Other speakers will include:

Walter W. Parker, LL.D., Cape Girardeau, president, Southeast Missouri State Teachers College, A Pedagogue Looks at the Doctors.
Dr. George Wilse Robinson Jr., Kansas City, The Addiction of Patients to Various Barbituric Acid Derivatives.
Dr. Roland M. Klemme, St. Louis, Accurate Differential Section for the Treatment of Trigeminal Neuralgia.
Drs. Wendell G. Scott and Sherwood Moore, St. Louis, Roentgen Kymography: A New Aid in the Diagnosis of Heart Disease.
Dr. Clinton K. Smith, Kansas City, A Revised Conception of Early Prostatic Hypertrophy.

At the public meeting, Tuesday evening, Dr. Ellis Fischel, St. Louis, will discuss "Early Recognition and Treatment of Cancer" and Dr. Edwin Lee Miller, Kansas City, "Appendicitis."

NEW MEXICO

State Medical Meeting at Clovis.—The annual session of the New Mexico Medical Society will be held at Clovis, May 13-15, with headquarters at the Hotel Clovis. The speakers announced on the program are:

Dr. Arthur E. Hertzler, Halstead, Kan., Surgery of the Thyroid.
Dr. Ray M. Balyeat, Oklahoma City, Therapeutic Value of Intratracheal Use of Iodized Oil Combined with Eliminative Measures and Specific Desensitization in the Treatment of Intractable Asthma.
Dr. Everett C. Fox, Dallas, Texas, Cancer of the Skin.
Dr. Harold T. Low, Pueblo, Colo., Vesical Neck Obstruction in Male Children.
Dr. Barton A. Rhinehart, Little Rock, Ark., Functional Disorders of the Gastro-Intestinal Tract.
Dr. Henry C. Gernand, Los Angeles, Conduct of Labor in Regard to Operative Intervention.
Dr. Meldrum K. Wylder, Albuquerque, Care of the New-Born.
Dr. William H. Daniel, Los Angeles, The Present Management of Cancer of the Rectum.
Dr. Melvin S. Henderson, Rochester, Minn., Modern Orthopedic Surgery.
Dr. Hugh G. Jeter, Oklahoma City, Blood Dyscrasias.
Dr. John A. Schoonover, Denver, subject not announced.

Dr. George W. Jones, Clovis, will be installed as president of the society at this meeting, to succeed Dr. Mallory B. Culpepper, Carlsbad.

NEW YORK

The Will Rogers Memorial Hospital.—The former National Vaudeville Artists Sanatorium at Saranac Lake became officially the Will Rogers Memorial Hospital February 25, when Will Hays presented the deed to Jesse H. Jones, treasurer of the Will Rogers Memorial Commission.

Society News.—The twenty-first annual meeting of the New York State Association of Public Health Laboratories will be held, May 10, at the Binghamton City Hospital. —Dr. Perrin H. Long, Baltimore, addressed the Medical Society of the County of Albany, March 24, on "The Use of Para-Amino-Benzene-Sulfonamide in the Treatment of Beta-Hemolytic Streptococcal and Other Infections." —At a meeting of the Onondaga Medical Society, Syracuse, April 6, the speakers were Drs. Abraham Clement Silverman, on "What's New About Scarlet Fever"; Joseph Ernest Delmonico, "Acute Pancreatitis," and Arthur N. Curtiss, "Treatment of Peripheral Vascular Disease." —Speakers who addressed the Syracuse Academy of Medicine, April 20, were Drs. Harry A. Steckel,

on "What's New About Dementia Praecox"; William E. Ayling, "Tuberculosis Case Finding in School Children," and Nathan P. Sears, "Carcinoma of the Cervix." —The New York State Conference of State, County and City Committees on Tuberculosis and Public Health of the State Charities Aid Association will be held at the Hotel Roosevelt, New York, May 11-13.

New York City

Personal.—Dr. Simon Flexner, emeritus director of the Rockefeller Institute for Medical Research, received the honorary degree of doctor of science at the recent centennial celebration of the University of Louisville School of Medicine, Louisville, Ky., April 3. —Dr. William Bierman was made a member of the Legion of Honor of France during the recent International Congress on Fever Therapy in New York, in recognition of his research on artificial fever. —Israel S. Kleiner, Ph.D., professor of physiology and biochemistry, New York Medical College and Flower Hospital, has received a grant from the Lucius N. Littauer Foundation to aid his studies of the male hormone.

Hospital Strikers Convicted of Disorderly Conduct.—Thirty-seven men and one woman were convicted of disorderly conduct and sentenced to thirty days in the city prison, March 24, after they had participated in sit-down strikes at the Brooklyn Jewish Hospital March 15 and 17. The sentences were suspended pending good behavior, which the judge defined as not doing anything to interfere with the routine of the hospital. Sixty-three strikers were discharged after they had refused to return to work, and those who declined to leave the hospital peacefully were arrested on the ground that, as they were no longer employed by the hospital, they were trespassing on private property. The workers included elevator operators, orderlies, laundry workers and maids.

NORTH DAKOTA

Health Officers Appointed.—Dr. Frank E. Bunting, Mandan, has recently been made health officer of Morton County. —Dr. Eugene E. Hamilton, New Leipzig, has succeeded Dr. Leonard B. Moyer as health officer of Grant County.

New Unit at State Tuberculosis Hospital.—A new unit to accommodate 125 patients will be placed in operation about May 10 at the North Dakota State Tuberculosis Sanatorium, San Haven. With the new addition the sanatorium will furnish service to 425 patients. The new unit is five stories high and of fireproof construction, faced with brick over tile. There is no wood in the walls and floors. The first floor is devoted to administrative offices, waiting rooms, examination rooms and surgery rooms; the second, third and fourth floors to wards for patients, and the fifth to a solarium. The entire cost of the unit was \$300,000, of which the state paid \$160,000 and the remainder was a PWA grant. Equipment will cost \$96,148.

OKLAHOMA

Personal.—Dr. Albert L. Davenport, Holdenville, has been appointed health officer of Hughes County to succeed Dr. Charles S. Wallace, Holdenville. —Dr. Clyde W. Beson, Claremore, former state health commissioner, has been appointed medical adviser to the state industrial commission. —Dr. Charles S. Bobo, Norman, was recently honored by a banquet given by the Cleveland County Medical Society in celebration of his eighty-first birthday.

Society News.—Drs. Lee Pettit Gay, St. Louis, and Herbert J. Rinkel, Kansas City, Mo., addressed the Tulsa County Medical Society, Tulsa, March 22, on "Peptic Ulcer: A New Etiological Concept" and "Treatment of Seasonal Hay Fever: The Evaluation of Secondary Factors in Seasonal Pollinosis," respectively. —Drs. Earl D. McBride and William K. Ishmael, Oklahoma City, addressed the Garfield County Medical Society, Enid, March 18, on arthritis, and Dr. Howard B. Shorbe, Oklahoma City, on immobilization and surgical care of fractures.

PENNSYLVANIA

Graduate Assembly in Harrisburg.—The annual graduate assembly presented by the Harrisburg Academy of Medicine will be held May 27 in the educational building at the state capitol. The following speakers will appear:

Dr. Hugh H. Young, Baltimore, The Prostate.
Dr. Philip W. Brown, Rochester, Minn., The Management of Diarrhea.
Dr. Clifford G. Grulee, Evanston, Ill., Breast Feeding.
Dr. Cary Eggleston, New York, Treatment of Heart Disease.
Dr. Isidor S. Ravidin, Philadelphia, Problems of Gallbladder Disease.
Dr. John P. Griffith, Pittsburgh, Diagnosis and Treatment of Hyperthyroidism.

Philadelphia

Award Presented to Dr. Turnbull.—The Strittmatter Award, given annually by the Philadelphia County Medical Society, was presented April 14 to Dr. William G. Turnbull, superintendent of the Philadelphia General Hospital since 1928. Dr. Turnbull was graduated from the University of Pennsylvania School of Medicine in 1906 and became superintendent of the Pennsylvania State Sanatorium for Tuberculosis at Cresson when it was established in 1913. Later he was appointed deputy state secretary of health with supervision over several state sanatoriums. He succeeded Dr. Joseph C. Doane in 1928 at Philadelphia General Hospital. The Strittmatter Award was established by Dr. Isidore P. Strittmatter to be given to the physician who has "made the most valuable contribution to the healing art, including remedial measures, surgical or medical." The presentation was at a dinner during the society's Postgraduate Institute. At this time Dr. John Shelton Horsley, Richmond, Va., delivered the John Chalmers Da Costa Oration on "Peritonitis."

Pittsburgh

Annual Meeting.—The Allegheny County Medical Society held its annual meeting at Hotel Schenley April 20. In the afternoon a scientific program was presented with addresses by Drs. Wingate Todd, Cleveland, on "Methods of Studying Constitutional Disturbances Associated with Allergy and Other Conditions"; James S. Taylor, Altoona, "Maternal and Fetal Mortality"; Leo H. Crip, Pittsburgh, "Allergy to Liver Extract," and Jesse B. Griffith, Pittsburgh, "Manipulation Treatment in Diseases of the Knee Joint." General Hugh S. Johnson, New York, was the speaker at the banquet.

Dedication of Mellon Institute Building.—The new building of the Mellon Institute for Industrial Research will be dedicated May 6. The program of the ceremony which will be held in Carnegie Music Hall, will include the following speakers: Dr. William P. Murphy, Boston; Harold C. Urey, Sc.D., professor of chemistry, Columbia University; Irving Langmuir, D.Sc., associate director of the research laboratory, General Electric Company, Schenectady, N. Y.; Andrew W. Mellon, former Secretary of the Treasury, and Richard K. Mellon, for the founders. Friday May 7 there will be a symposium on recent progress in science in Carnegie Music Hall, in which the speakers will include Sir Frederick G. Banting, Toronto, Ont.; Dr. William W. G. MacLachlan, Pittsburgh; Frank B. Jewett, Ph.D., Bell Telephone Laboratories, New York, and George O. Curme Jr., Ph.D., vice president and director of research, Carbide and Carbon Chemicals Corporation, New York. The building will be open to the public Saturday and Sunday, May 8-9.

TEXAS

State Medical Meeting at Fort Worth.—The seventy-first annual session of the Texas State Medical Association will be held in Fort Worth, May 11-13, with headquarters at the Hotel Texas. The following guest speakers will address general sessions Tuesday morning, Wednesday and Thursday afternoons:

Dr. Charles Gordon Heyd, New York, President, American Medical Association, on The American Medical Association—Your National Society.
Dr. Edward Clay Mitchell, Memphis, Tenn., Infection and Immunity with a Résumé of Prevention of Contagion.
Dr. Walter E. Dandy, Baltimore, Brain Tumors.
Dr. William Warner Watkins, Phoenix, Ariz., Haliteresis as a Medical Problem.
Dr. Francis E. Le Jeune, New Orleans, The Significance of Hoarseness (Motion Picture).
Dr. Joseph Rigney D'Aunoy, New Orleans, Lymphogranuloma Inguinale.
Dr. Lewis J. Moorman, Oklahoma City, Diagnostic Problems in Diseases of the Respiratory Tract.
Dr. Virgil S. Counsellor, Rochester, Minn., Cancer of the Reproductive Organs of Women.
Fred Hale, M.S., College Station, Texas, The Relation of Maternal Vitamin A Deficiency to Microphthalmia in Pigs.
Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Public Health Control of Syphilis.

Several of the guests will also address section meetings. Wednesday there will be three "clinical luncheons" given by the sections in honor of their guests and on Thursday a combined sections luncheon. The section on public health will present a symposium on syphilis, with Drs. James W. Bass, Everett C. Fox and Arthur G. Schoch, Dallas; Leroy B. Duggan, Houston, and George W. Cox, Austin, state health officer, as the speakers. The section on radiology and physical therapy will have symposiums on pneumonia and bone tumors. Thursday morning a tumor clinic will be held in cooperation with the Texas State Pathologic Society. The woman's auxiliary will hold its nineteenth annual session under the

presidency of Mrs. Robert B. Homan, El Paso. The president's reception will be at the Hotel Texas, Tuesday evening May 11, honoring Dr. Howard R. Dudgeon, Waco, president of the state association. Monday evening the Tarrant County Medical Society will entertain the visiting physicians. Related organizations that will meet during the week are the Texas Railway Surgeons Association, Texas Neurological Society, Texas State Heart Association, Texas Dermatological Society, and a conference of county and city health officers called by the state health officer.

GENERAL

Society News.—The twenty-second National Recreation Congress will be held in Atlantic City, May 17-21, with headquarters at the Ambassador. The National Congress of Parents and Teachers will hold its forty-first annual meeting in Richmond, Va., May 3-7. The Academy of Physical Medicine will meet, October 19-21, at the Hotel Walton, Philadelphia.

Meetings in Atlantic City.—The place for the annual luncheon of Phi Delta Epsilon during the annual session of the American Medical Association at Atlantic City has been changed from the Ritz-Carlton to the Ambassador, Thursday, June 10, at 12:30 p. m.—The annual Alpha Omega Alpha dinner during the annual session of the American Medical Association will be held at the Hotel Ambassador, Atlantic City, Thursday evening June 10. Dr. Walter Bradford Cannon, Boston, will be the speaker, on "The Value and Harm of Scientific Controversy."

Association of the History of Medicine.—The thirteenth annual meeting of the American Association of the History of Medicine will be held at Haddon Hall, Atlantic City, N. J., May 3. This meeting will commemorate William Wood Gerhard's differentiation of typhus from typhoid in 1837. The program will include the following speakers:

Dr. William S. Middleton, Madison, Wis., William Wood Gerhard.
Drs. George M. Dorrance and John W. Bransfield, Philadelphia, How the Ancients Treated Fracture of the Mandible.
Dr. Logan Clendening, Kansas City, Mo., The Medical Winning of the West.
Dr. Michael Leo Ravitch, New York, Metchnikoff, the Great Scientist and Nihilist.
Dr. Henry E. Sigerist, Baltimore, Medical History in the United States.
Dr. Maude E. S. Abbott, Montreal, More About Osler.

Child Welfare League Appoints Pediatrician.—Dr. Florence A. Browne, Detroit, has been appointed pediatrician to carry out a consultation and field service for the Child Welfare League of America under a grant from the Commonwealth Fund. Dr. Browne graduated from Johns Hopkins University School of Medicine, Baltimore, has served as pediatrician of the Michigan State Department of Health and has been in pediatric practice in New York. She began her service with the league March 1. The need for this service has become acute since the cessation of the program of the American Child Health Association, the league points out. It will now be possible to aid organizations caring for children in the development of plans for physical examinations of children, immunization, preparation of health records, and other health services.

Automobile Fatalities in Major Cities.—The U. S. Bureau of the Census reports that 9,599 deaths from automobile accidents occurred during 1936 in 131 major cities, a reduction of 178 from the number reported in 1935. During the first half of 1936, fatalities were reduced below the 1935 figures in sixty-three cities, but in the latter half of the year the toll rose rapidly. New York decreased its fatal accidents by 12.9 per cent, and Chicago by 8.8 per cent. Among other large cities that reported reductions were Baltimore, 12.8 per cent; Boston, 6.9; Camden, N. J., 43.3; Dallas, 15.1; Des Moines, 48.7; Newark, 17; New Orleans, 30.5; Omaha, 59.5; St. Louis, 38.9, and Worcester, Mass., 28.6. San Francisco reported 50 per cent more deaths, ninety in 1936 as compared with sixty in 1935. Other increases over the previous year were Albany, 23.8 per cent; Birmingham, 28.6; Detroit, 19; Milwaukee, 19.6; Philadelphia, 13.5; Pittsburgh, 4.1, and Wilmington, Del., 36.4.

Conference of Health Authorities.—The annual Conference of State and Provincial Health Authorities of North America was held April 5-6, in Washington, D. C., at the U. S. Public Health Service Building. Dr. Robert H. Riley, Baltimore, state health director of Maryland, was elected president; Dr. Maysil M. Williams, Bismarck, state health officer of North Dakota, vice president, and Dr. John A. Ferrell, New York, was reelected field secretary. The program included a symposium on flood health problems by Drs. Arthur T. McCormack, Louisville, Ky.; Wilson C. Williams, Nashville,

Tenn., and Walter H. Hartung, Columbus, Ohio, health officers of their respective states. The following papers, among others, were presented:

- Dr. Thomas Anwyl-Davies, London, Public Health Control of Syphilis in Great Britain.
 Dr. Ambrose J. King, London, Public Health Control of Gonorrhea in Great Britain.
 Dr. Rufus J. Cole, New York, Possibilities for Pneumonia Control as Indicated by Present Scientific Knowledge.
 Dr. Roscoe R. Spencer, U. S. Public Health Service, The U. S. Public Health Service Program of Public Health Education.
 Dr. Halbert L. Dunn, U. S. Bureau of the Census, Resident Death Rates and Public Health.

Tri-State Hospital Assembly.—The Tri-State Hospital Assembly, sponsored by the hospital associations of Illinois, Indiana and Wisconsin, will be held at the Hotel Sherman, Chicago, May 5-7. Subjects to be discussed include "The Administrative Organization of the Hospital," "Maintaining Professional Service Standards in Hospitals" and "Organization and Arrangement of the Physical Therapy Department with Regard to Efficiency, Economy and the Budget." In addition to round table and panel discussions presented by the constituent associations, the following, among others, will speak:

- Dr. Clement C. Clay, Chicago, The Adoption of a Standard Insurance Form for Proof of Death and Disability.
 Dr. William H. Walsh, Chicago, Correct Designing of a Medical Record Library.
 Chester F. Farmer, M.S., Chicago, A Micromethod for the Estimation of Ascorbic Acid in Blood.

At the annual banquet Thursday evening, sponsored by the Chicago Hospital Association, the speakers will be Drs. Philip F. Schneider, Evanston, Ill., and Israel Davidsohn, Chicago; their subjects are, respectively, "An Evaluation of Tests Being Used to Determine Pregnancy" and "Infectious Mononucleosis: Its Hematologic and Serologic Diagnosis."

PUERTO RICO

Society News.—Dr. Isaac F. Gonzalez Martinez, San Juan, was recently reelected president of the Puerto Rico chapter of the Pan American Medical Association; Dr. Jose Rodriguez Pastor, San Juan, vice president, and Dr. Rafael Rodriguez Molina, San Juan, secretary.

University News.—Nicholas Murray Butler, Ph.D., president of Columbia University, New York, paid a visit of inspection recently to the School of Tropical Medicine of the University of Puerto Rico, which is under the auspices of Columbia. The university conferred on Dr. Butler the honorary degree of doctor of laws, honoris causa. Dr. Alwin M. Pappenheimer, professor of pathology in the College of Physicians and Surgeons at Columbia, and Dr. Frederic M. Hanes, professor of medicine, Duke University School of Medicine, Durham, N. C., have recently visited the school for lectures and research.

FOREIGN

Course in Malarology in Rome.—The Institute of Malarology, Ettore Marchiafava, at the Policlinico Umberto I, Rome, will offer special courses to graduate physicians from July 15 to September 20. The lectures will be given in French, but interpreters will be available. There will be lectures and demonstrations of hematology, protozoology, the parasites of malaria and microscopic diagnosis, entomology, epidemiology and prophylaxis. The course will also cover malarial treatment of mental diseases, visits to malaria patients, visits and residence in an experiment station and in a center of induced malaria. Special steamship and railroad rates may be obtained, a reduction of about 50 per cent for individuals and 70 per cent for groups of eight or more. Information as to steamship rates, lodging and other details may be obtained by writing to the Royal Consul General of Italy, 626 Fifth Avenue, New York. Applications must be made before June 20.

World Congress on Documentation.—A World Congress of Universal Documentation is being organized to take place in Paris, August 16-21, under the auspices of an International Committee on Documentation. Defining the term documentation, an announcement includes all documents, manuscripts printed or otherwise recorded, catalogues, indexes, bibliographies and the methodical use of them in archives, libraries, documentation centers and museums. All those concerned in this large field are interested in a rational organization of documentation, it is stated, and various organizations have been working toward this end. The purpose of the congress will be to inquire into the present state of things and to examine principles, programs and methods, to draw up a minimum plan of work and service and to make a collective agreement to uphold any decisions made. Watson Davis, director of Science Service, Washington, D. C., is the American member of the International Committee of Documentation.

Government Services

Colonel Metcalfe Named Assistant Surgeon General

Col. Raymond F. Metcalfe, chief of the surgical service, Walter Reed General Hospital, Washington, D. C., has been appointed assistant to the surgeon general with the rank of brigadier general. He succeeds Brig. Gen. M. Augustus W. Shockley, who retired February 28, on his own application, after more than thirty years' service. A native of Salamanca, N. Y., the new assistant surgeon general graduated from the University of Buffalo College of Medicine in 1900 and the following year began his service with the army as assistant surgeon. During the World War, General Metcalfe served in France as chief surgeon of the thirty-sixth division and later of the First Army, participating in the Oise-Aisne and Meuse-Argonne operations. For his service in connection with the suppression of influenza epidemics in the American Expeditionary Forces, he was awarded the Distinguished Service Medal.

Annual Report of Children's Bureau

A summary of the annual report of the Children's Bureau of the U. S. Department of Labor lists recommendations based on activities of the bureau and on the increase in its work brought about by the Social Security Act. Under the heading "Social Security for Children," the report recommends: (1) a public welfare program extending throughout every state and including provision for public assistance for those whose economic needs cannot be met by private or public employment; (2) assessment of resources for medical care, especially care available for mothers and children; (3) study of methods of care for crippled children; (4) development of adequate medical and social services for blind and deaf children; (5) provision for feeble-minded, epileptic and psychopathic children, and (6) extension of the provisions of the maternal and child welfare provisions of the Social Security Act to Puerto Rico. The report repeats a recommendation previously made for an inquiry into maternal and infant mortality. Administration of maternal and child welfare should be developed especially along the following lines, the report points out: just distribution of financial responsibility, wise leadership from the larger units, flexibility of programs, and staunch adherence to the merit system of appointments. The report finally urged ratification of the Child Labor Amendment to the Constitution by the remaining states necessary to put the amendment into effect and development of better methods of administering the law.

New Army Medical Officers

As a result of a recent examination, the following officers of the reserve corps have been commissioned as first lieutenants in the medical corps of the regular army:

- | | |
|--|---|
| Robert J. Benford, Brooklyn, N. Y. | Gottlieb L. Orth, Fort Belvoir, Va. |
| Albert A. Biederman, Fort Leavenworth, Kan. | Donald B. Peterson, Grand Marais, Minn. |
| Theodore M. Carow, Fort Thomas, Ky. | William J. L. Porcher, Denver, Colo. |
| Edward A. Cleve, Fort Knox, Ky. | Kyle A. Radtke, formerly Fort Townsend, Wash. |
| William F. Conway, Washington, D. C. | Merrill J. Reeh, Sultan, Wash. |
| Lester Orville Crago, Fort Benjamin Harrison, Ind. | Weldon K. Ruth, Fort Sill, Okla. |
| Warren H. Diessner, Oswego, N. Y. | Dean Schamber, Fort Snelling, Minn. |
| Claude C. Dodson, El Paso, Texas. | Lewis C. Shellenberger, Carlisle, Pa. |
| Charles J. Farinacci, Baltimore, Md. | Albert W. Shiflet, Casper, Wyo. |
| Edwin M. Goyette, Northfield, Vt. | Scott M. Smith, Shreveport, La. |
| Alfred A. Grebe, El Paso, Texas. | James P. Sullivan, formerly at Chevy Chase, Md. |
| Robert J. Hoagland, San Antonio, Texas. | Myron J. Tremaine, Youngstown, N. Y. |
| William F. Holmes Jr., Fort Sill, Okla. | Harold V. Weatherman, Fort Douglas, Utah. |
| Rex C. House, Lawton, Okla. | Edward R. Wernitznig, Bellefonte, Pa. |
| Eugene C. Jacobs, River Forest, Ill. | William E. Wilkinson, Frankfort, N. C. |
| Bruno B. Jastremski, Winthrop, N. Y. | William D. Willis, Dallas, Texas. |
| Marshall N. Jensen, Omaha, Neb. | Paul O. Wells, San Antonio, Texas. |
| Douglas B. Kendrick Jr., Edgewood, Md. | Lloyd E. Gould, Grand Canyon, Ariz. |
| Ronald F. Kirk, Fort Logan, Colo. | Beverly Dixon Holland, Fort Stevens, Ore. |
| Emmert C. Lentz, Los Angeles, Calif. | Santino J. Lerio, Fort Howard, Md. |
| Lee P. Mayes, Cape Cottage, Me. | Donald E. Casad, Banning, Calif. |
| James G. Moore, Sault Ste. Marie, Mich. | Charles O. Bruce Jr., Lincoln, Neb. |
| Harold A. Myers, Des Moines, Iowa. | Nicholas F. Atria, Fort Benning, Ga. |
| Gus W. Neece, Fort Moultrie, S. C. | Joseph Rich, Newport, R. I. |
| Kenneth R. Nelson, Fort George G. Meade, Md. | |

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 3, 1937.

The Value of Irradiation in Malignant Disease

At the Royal Society of Medicine, Mr. Sampson Handley read a paper on the value of preoperation and postoperative irradiation in malignant disease. He could not draw any sharp line between radiation by x-rays and radiation by radium, though he thought the latter more effective in quality and subject to fewer drawbacks; but each method had its field. Mr. Handley mentioned three cases in which, subsequent to removal of internal abdominal malignant growths, nodular lumps appeared in the abdominal scar itself. Since radium can destroy massive implantation recurrences, it would a fortiori, if applied just after operation, destroy the microscopic cancer cells which are the seeds of recurrence. For this purpose Mr. Handley considered high voltage x-rays as effective as radium and more convenient. The facts of implantation recurrence alone provided a wide field for the postoperative use of high voltage x-rays. There were indeed few cases in which the possibility of implantation could be excluded. In all cases of gastric, intestinal or pelvic malignant disease, as well as in breast cancer and in operations for malignant glands in the neck, a short course of high voltage x-rays should be applied to the scar after operation. Some surgeons would prefer insertion of radium tubes in the wound at the time of operation.

Preoperative irradiation need hardly be considered with regard to implantation recurrence, unless it was believed that it could be made so effective that every cell in the growth could be deprived of the power of proliferation. But then operation would be superfluous. In cases of doubt whether operative removal of a disseminating growth was complete, the crucial question was whether it was better to apply supplementary radiation before or after operation. Mr. Handley referred mainly to cancer of the breast. In dealing with the question he had the difficulty that he never advised preoperative irradiation, except in rare cases as a possible means of converting a fixed inoperable growth into a mobile one. His reasons against preoperative irradiation were as follows: It involves delay in performing the operation, giving time for the deep microscopic extensions of the growth, its most dangerous part, to make further advance. Though the primary growth might shrink under the x-rays, the evidence was that dissemination was unchecked. Even by modern apparatus and methods it was difficult to convey to any considerable distance beneath the skin a lethal dose of x-rays to carcinoma cells. This applied to attempts to irradiate carcinoma cells in the pectoral fascia or muscle through a voluminous breast. But after removal of the breast even deeper layers, such as the intercostals and pleura, are brought near the skin and exposed to the full force of irradiation. The apical glands of the axilla and the internal mammary glands were so sheltered that Mr. Handley doubted whether they could be dealt with by any dose of x-rays that the overlying skin could tolerate. But the apical glands can be removed and the internal mammary glands can be treated at the time of operation by interstitial radium tubes. Mr. Handley had found the latter effective.

Mr. Handley considered that the best hopes for progress in treatment lay in public education as to the necessity for prompt treatment of suggestive lumps and in a closer study by radiologists, as well as by surgeons, of the details of dissemination, and in the routine application after operation of a short prophylactic course of x-rays at at least 180,000 volts.

A Bureau of Geographic Medicine

Correspondence has taken place in the *British Medical Journal* on the need for a bureau of geographic medicine. Dr. F. C. Eye, who began the discussion, said that clinicians must long have been tantalized by reading isolated observations such as "The cultured Chinese never suffer from high blood pressure." He wanted to know if such statements were reliable. He envisaged "The Central Bureau of Geographical Medicine," which would coordinate and digest such observations from all over the world. The suggestion was supported by Dr. W. P. Kennedy, professor of physiology in the Royal College of Medicine in the University of Baghdad, who has found significant differences between the blood of British subjects in Iraq and in Britain. The explanation had not been elucidated, but the facts appeared to point to climatic factors as responsible. Professor Kennedy has had considerable difficulty in finding literature on hematologic standards in different parts of the world. Prof. L. T. Ride, who occupies the chair of physiology in the University of Hong-Kong, points out that there is in existence an organization which to some extent meets the need expressed. Those who work among non-European races soon recognize that physiologic constants cannot be applied from one race to another. At the meeting of the International Federation of Eugenic Organizations in Zurich in 1934 this problem was discussed and the result was the formation of the Committee on Anthropological Physiology, of which Professor Ride is chairman. The aims are to stimulate the investigation of physiologic constants among various races, to make contact with the workers on this subject in different parts of the world, to ensure the use of similar methods so that comparative data may be of greater value, and to provide for meetings of the investigators. The committee has members in the United States (Prof. L. H. Snyder of Columbus, Ohio, Prof. F. G. Benedict of Boston), China, India, Japan, the Netherlands Indies, New South Wales, South Australia and Denmark.

The Cambridge Chair of Physiology

The Cambridge school of physiology has long been the leading one in Great Britain. The professor of physiology, Sir Joseph Barcroft, F.R.S., will this year retire. He has played a great part in maintaining the tradition of the school. His early investigations were concerned mainly with the carriage of oxygen by the blood and with chemical changes in the salivary glands and kidneys, which he found used more oxygen when active than when at rest and which liberated metabolites that controlled their blood supply. In order to study the gases in small samples of blood or other tissues he invented a differential manometer, known everywhere as Barcroft's apparatus. For many years he has represented Cambridge against Oxford in favor of the view that the passage of gases through the epithelium of the pulmonary alveoli is a simple physical process and that the lungs cannot take up oxygen unless its pressure in the air is greater than in the blood. In support of this view he led an expedition up high mountains and exposed himself for many days to low oxygen pressure in a glass box. He has shown that the spleen plays an important part in the circulation as a reservoir of blood, which is released in emergencies, and he has added much to our knowledge of the oxygen supply of the fetus in utero.

Sir Joseph Barcroft is succeeded by another eminent physiologist, E. D. Adrian, F.R.S., who is Foulerton research professor of the Royal Society. Before the war he worked at Cambridge with Lucas on the problems of the motor impulses in nerves. He left Cambridge and became resident medical officer at the National Hospital for Nervous Diseases. In 1919 he began his well known work "The Physical Basis of Sensation." He took advantage of the new methods for ampli-

fying electric currents and tapped the messages in nerves. He thus analyzed sense organs in a way that was not previously possible. In recognition of this work he received the Nobel prize for medicine in 1932. In 1935 he published another important work, entitled "The Mechanism of Nervous Action."

The Marie Curie Hospital

In 1929 a hospital, staffed by women, was founded in London for the radiologic treatment of women suffering from cancer and was appropriately named the Marie Curie Hospital, after the woman who discovered radium. Queen Mary, who is patron of the hospital, has opened in it new and enlarged laboratories. Lord Dawson, president of the Royal College of Physicians, who presided at the ceremony, said that this radium hospital, staffed by women physicians, had already done much excellent work. Of its thirty-nine beds, twenty-nine were devoted to the needs of uterine cancer. The results were encouraging. Of the cases taken at an early stage, disease was absent in as many as 85 per cent at the end of five years. Of the cases in which the disease was firmly established, the same freedom was shown in as many as 65 per cent. Even among those in whom the disease was advanced on reaching the hospital the results were encouraging, at times astonishingly so. Mlle. Eve Curie said that her mother had always been much interested in the work of the hospital, though she regretted that at its foundation it had no research laboratory.

Road Accidents in 1936

Details of the road accidents in 1936 have just been published. There were in Great Britain 198,978 road accidents in which persons were killed or injured, an increase of 3,086 over the preceding year. The persons killed numbered 6,561, an increase of fifty-nine, and the injured numbered 227,813, an increase of 6,087. Of the vehicles to which the accidents were attributed, private automobiles formed the largest group, with 64,529 accidents, an increase of 2,520 on the previous year. Pedal cycles were involved in 61,932 accidents, an increase of 1,493; motorcycles in 24,990, a decrease of 695. Of the 6,561 persons killed, 3,068 were pedestrians, an increase of thirty over the previous year. There were 1,498 pedal cyclists killed, an increase of ninety-eight. Of the injured, 74,576 were pedestrians, an increase of 399; 71,193 were pedal cyclists, an increase of 2,141. Fatal accidents numbered 6,359, an increase of forty-five. There were more in December (677) than in any other month.

The Protection of the Civilian Population Against Air Raids

As shown in previous letters, preparations for the protection of the civilian population against air raids go on unceasingly. Throughout the country men and women in large numbers are being trained in first aid and decontamination duties, and 300,000 air raid wardens are being appointed to direct the people in emergencies. A silver badge is being issued to men volunteers and a silver brooch to women. Gas masks are being turned out at the rate of 500,000 a week.

In a communication to the *Lancet*, Dr. J. A. Ryle, professor of physics in the University of Cambridge, points out that while so much is being done in the instruction of physicians, police and others in antigas measures, little is being done in arranging for the collection, sorting, evacuation and treatment of the numerous casualties that must occur in spite of all the measures taken. One or two large scale raids with gas, incendiary bombs and high explosives might easily fill all the hospitals of a city to overflowing, and the hospitals themselves might not escape damage. In addition to aid posts and clearing stations, fleets of ambulances would be needed, and a circle of schools and other suitable buildings well beyond the outskirts of exposed towns would have to be equipped as hospitals.

PARIS

(From Our Regular Correspondent)

April 3, 1937.

American Hospital of Paris in Need of Support

An earnest appeal to all American residents of France, as well as to those who are in the habit of passing several months of the year in this country, to contribute to the support of the American Hospital of Paris was made recently by Arthur T. Kemp, president of the institution, at the annual meeting of the hospital board of governors. An appeal was made to Americans who reside abroad or visit Europe to subscribe \$20 a year as ordinary members or \$500 as life members. The American Hospital, out of its special and general funds, rendered hospital services to needy patients unable to pay the usual hospital charges in whole or in part, representing in the aggregate an amount of \$68,897, or 1,501,972 francs, of free service at the present rate of exchange. Many improvements have been effected in the hospital during the last year, including a new ventilating system as well as dish-washing and sterilizing machinery in the kitchen, the establishment of a cafeteria for the nursing and office staff, and the addition of new equipment to the department of hydrotherapy. Mr. Kemp was reelected president and Mr. E. B. Close, who has voluntarily served as manager for the past three years, was thanked for his excellent work and reelected first vice president. Dr. E. L. Gros was reappointed chief of staff.

Operative End Results in Advanced Gastric Cancer

At the February 19 meeting of the Société médicale des hôpitaux, a series of cases were reported by Dr. René Gutmann in which gastrectomy for advanced cancer had been performed from three to twelve years ago. The presence of severe anemia should not be regarded as a contraindication, because with the aid of transfusions and operations under local anesthesia many patients can be operated on now who were considered poor risks formerly. As the result of eighty-eight gastrectomies for cancer performed at the Gosset clinic up to 1935, thirteen patients died during the first year, twenty-seven were living after two to five years, eighteen more than five years, and seven more than eight years after the operation. Extensive filling defects on radiologic examination do not mean that early recurrence is more likely to take place than when only small filling defects are found. A small cancer can be accompanied by extensive liver metastases and be fixed, whereas an extensive cancer may be found perfectly mobile without liver metastases. The most important point to determine in considering operability is how much of the stomach is not involved and where the resection can be done. With the present development of radiologic technic much information can be given as to operability, but the final decision as to the latter depends on the results of exploration of the upper part of the abdomen at the time of operation. The presence of enlarged lymph nodes alone is not a contraindication, because only half of them were found to be cancerous on microscopic study of the resected stomach as Professor Gosset's clinic.

Conquest of Tropical Diseases

An instructive lecture on the sanitary organization of the Italian army during its recent campaign in Ethiopia was given at the Sorbonne (University of Paris) February 21 by Prof. Aldo Castellani. Although there are many plateaus (up to 4,200 feet above sea level) in Ethiopia, the major portion of the military operations took place in the lower sandy or marshy regions under tropical conditions. The small number of deaths (599 for 500,000 men) is without precedent in the history of wars in an equatorial climate. During the World War the Serbian army lost 25 per cent of its active troops from typhus; hence a mortality of 100,000 for 500,000 men would not have been considered excessive for the Italian army. The latter had

135 base hospitals, fifty-five mobile hospitals, eleven stationary and fifteen motorized (mobile) radiologic centers, four large ordinary diagnostic laboratories, twelve disinfection centers, six disinsectization stations and 136 water purification centers. Special attention was given to the care of the teeth of the soldiers at odontologic centers. In addition, there were eight air conditioned hospital ships. The medical personnel included 2,500 physicians and pharmacists, 15,000 hospital orderlies and 2,584 nurses. The prophylactic treatment of malaria was carried out by giving large doses (0.65 Gm.) of quinine to every soldier and controlling its absorption by urine examinations. There were 1,941 primary malarial infections, 1,095 relapses and twenty-three deaths from pernicious malaria among this number of cases. Only 429 cases of dysentery required hospitalization and there were no deaths. The majority of cases were of amebic origin.

As the result of the routine use of an associated (typhoid, paratyphoid and cholera) vaccine combined with boiling and constant surveillance of drinking water, not a single case of typhoid was observed. The same was true of typhus exanthematicus, although there are 20,000 cases annually among the Ethiopian natives. There were seventeen cases of recurrent fever and only one of variola. Insolation was fatal in seven of twenty-three cases. The ample distribution of lemons and fresh meat prevented diseases such as beriberi, pellagra and scurvy, which were prevalent among native soldiers and their families. There were only five cases of tetanus and none of plague or cholera. War injuries caused the death of 119 officers and 980 soldiers. The death of twenty-two officers and 577 soldiers was due to disease, drowning and bites of insects and snakes. These statistics are a glowing tribute to military medicine and especially to Professor Castellani, the leading spirit in this sanitary organization.

Diagnosis of Paroxysmal Hemoglobinuria

At the February 12 meeting of the Société médicale des hôpitaux, two cases were reported by Brule, Hillemand and Gaube which show the difficulties in making a diagnosis of paroxysmal hemoglobinuria. The first patient was a man, aged 24, who on Nov. 3, 1934, had suddenly voided urine that appeared to contain blood. Examination of the urine revealed a marked albuminuria, some leukocytes and granular casts, but no red cells. The following day an intense icterus appeared. He was seen for the first time by Brule and associates sixteen days later. A subicteric hue was still present, the urine showed only urobilin, and the blood urea was normal. He left the hospital apparently well but returned Aug. 15, 1935, stating that he had noticed clay-colored stools. The urine again showed only the presence of urobilin, the liver was slightly enlarged, the spleen was normal and there was a slight anemia. A tentative diagnosis of hepatitis or incomplete common duct obstruction having been made, an exploratory laparotomy was performed with negative results. The subicteric color persisted but the general condition was greatly improved following a cholecystostomy. The patient returned fifteen months later with the history of having had two attacks of jaundice associated with very dark colored urine, but without acholic stools. He was readmitted to the hospital, where examination of the urine showed a hemoglobinuria. The subicteric color persisted in the intervals between acute periods of hemolysis. The blood study of this patient was taken up following presentation of the second case. This patient was a man, aged 52, who gave the history of malaria and who had been pensioned for what had been diagnosed as chronic hematuric nephritis. Since 1925, following every exposure to cold, dark red urine was voided. A tentative diagnosis was made, on the basis of this history, of paroxysmal hemoglobinuria. During the interval between attacks when the patient was first seen by Brule and his associates, nothing abnormal was found. The malaria had been

contracted during the war and there was a history of an attack of hemoglobinuric biliary fever. The tentative diagnosis of paroxysmal hemoglobinuria was confirmed (during the interval between attacks) by the positive Donath and Landsteiner reactions, which they consider pathognomonic when a patient is seen between the attacks of paroxysmal hemoglobinuria.

In the first of these two cases the blood study should have led to the diagnosis of hemolytic icterus because the two reactions cited appeared to be negative and the globular resistance seemed lowered. But in making these two reactions with all of the precautions so well investigated by Vidal, Abrami and Brule, these reactions will always be found positive in hemoglobinuria during an interval between attacks. The globular fragility is of no importance; hence this notion ought to be revised. If one takes the precaution to keep the red corpuscles constantly at a temperature of 37 C., the globular resistance will always be found normal. Vidal, Abrami and Brule have called attention to this detail for some time. In certain cases of hemoglobinuria, the slightest lowering of temperature suffices for the red corpuscles to be sedimented (fragilized) by the serum. These causes of error are not as well known as they deserve to be; hence all the reports of cases of paroxysmal hemoglobinuria with globular fragility and negative Donath and Landsteiner tests need to be revised. An essential difference exists between hemolysis with globular fragility as observed in true hemolytic icterus and the hemolysis due to action of the plasma as it is found in paroxysmal hemoglobinuria.

Infarct of the Mesentery and Small Intestine Due to Vascular Spasm

During the past two years, some instructive clinical and experimental observations have been reported by Professors Grégoire and Binet showing that in certain cases presenting the symptoms of acute occlusion of the mesenteric vessels, the underlying condition was of transitory character, the result of vascular constriction of vasomotor origin, which yielded to injections of epinephrine. At the February 3 meeting of the Académie de chirurgie Professor Grégoire added two analogous cases, observed respectively by Loverdos of Greece and by Asselin of Chateauroux, France.

In the Loverdos case a man, aged 68, had never been ill before. The onset was acute, with severe epigastric pain, nausea, small rapid pulse, rigid abdomen and symptoms of shock. The complete obstipation and the accompanying symptoms led to the diagnosis of acute intestinal obstruction. When the abdomen was opened a large amount of bloody serum escaped. One of the loops of small intestine presented a hemorrhagic appearance and the corresponding mesentery a greenish color. No observations were made as to whether a pulsation still existed in the mesenteric vessels of this loop. Some intravenous injections of 20 per cent sodium chloride and of epinephrine were followed by rapid recession of the symptoms of shock and recovery.

In Asselin's case a woman, aged 65, had acute abdominal symptoms that led to a diagnosis of intestinal obstruction, probably due to a neoplasm. Abdominal examination revealed a tender mass in the umbilical region. The clinical symptoms were those of severe shock, as in the recent case of Loverdos and the previously reported cases of Grégoire. A very fetid bloody fluid escaped when the abdomen was opened. Almost all of the small intestine was dark, almost greenish, and the corresponding mesentery presented a number of hemorrhagic foci resembling in some places gangrenous areas. There was marked congestion of the mesenteric vessels. The injection of 1 cc. of 1:1,000 epinephrine intravenously was followed almost immediately by the appearance of an almost normal color of the intestine and mesentery. The abdominal (parietal) incision was closed and 20 cc. of a hypertonic solution (20 per

cent) of sodium chloride given intravenously. The next day the symptoms of shock had disappeared, but colicky abdominal pain continued and the patient died four days after the operation. Necropsy was not obtained. In commenting on these two cases, Professor Grégoire stated that the sudden onset in a previously healthy person, as in the first case, differentiated it from that due to embolism or thrombosis of the mesenteric vessels. The weak, rapid pulse and marked shock that characterize an intestinal apoplexy are quite different from those of an incipient ileus due to occlusion of the mesenteric vessels. In the second case, operative intervention and the injection of epinephrine to combat the vascular spasm was too late to be of avail. Grégoire pleaded for abstention of the giving of morphine in acute abdominal cases. It relieves the pain but masks the underlying pathologic condition.

The Radiologic Appearance of Acute Pulmonary Edema

Only brief references can be found in textbooks on radiology to acute pulmonary edema. A case reported by Meldolesi, in which roentgenograms were made after a few hours, is the only one to be found in the literature; hence the report of another is of considerable interest. At the February 5 meeting of the Société médicale des hôpitaux, Marcel Lelong and Jean Bernard showed a number of films of a child 8 years of age suffering from acute pulmonary edema as a complication of acute nephritis. The pulmonary condition appeared suddenly at the onset of the renal conditions and was accompanied by hematuria, marked dyspnea and edema of the extremities. The acute nephritis was secondary to a severe throat infection. The chest films were taken not only at the height of the nephritis, but also during the period of recession of the acute renal symptoms. The chief radiologic feature of the acute pulmonary edema was a generalized disappearance of the pulmonary transparency, less in the peripheral portions than in the region of the hilus. The juxtahilar area was especially opaque, the shadow being uniform. Parallel with the improvement of the general condition, the lung opacity cleared up first at the periphery and then toward the hilus on each side. The opacity can be best explained as due to the transudate in the alveoli.

In the discussion, Laubry stated that acute pulmonary edema in this case was not of cardiac but of peripheral origin; i. e., due to the acute nephritis and hence of vascular origin.

BERLIN

(From Our Regular Correspondent)

March 29, 1937.

The Increase in Diphtheria

The National Bureau of Health has published figures which indicate that the number of diphtheria cases increased from 64,138 in the year 1932 (9.9 per 10,000 of population) to 149,971 in 1936 (22.4 per 10,000 of population). The morbidity from diphtheria has more than doubled since 1932. The opinion that physicians often fail to diagnose the disease correctly in its early stages and consequently resort to administration of serum at too late a stage is not supported by the statistics. The rise in the number of fatalities does indicate, however, that the patient's parents are prone to call in the doctor only after the disease has gained too great headway. It is the official view of the National Health Bureau that a vast majority of the diphtheria victims in 1935 could with certainty have been saved if they had received proper medical attention in time and if antidiphtheritic serum had been speedily administered. Education of the public can be carried on chiefly through the consulting centers for mothers and the welfare centers for nurslings and small children, as well as by the distribution of the pamphlets on diphtheria that were issued by the National

Health Bureau in 1935. If every case of diphtheria would receive specific treatment on the first or second day of illness, many fatalities would be avoided.

Congenital Dislocation of the Hip

Professor Gocht, Berlin, ordinarius in orthopedics, lectured on congenital dislocation of the hip before the Berlin Society of Pediatricians. He emphasized the importance of early diagnosis of any disturbance of growth in the iliac region. Serious alterations often ensue if a joint has been injured by reducing operations. Some damage is often unavoidable if the child is too old at the time of the reduction or if considerable displacement of the hip components has taken place. After early treatment of incipient or threatened luxation of the hip, the roentgen visualization ought not to reveal the slightest support for any pathologic process. Early diagnosis is facilitated by the following considerations: The leg in question appears somewhat too short; furthermore there will be a certain outward rotation, the movement of abduction is restricted, and the axial bearings of the leg pass by the acetabulum (in the middle of the ligamentum inguinale). The iliac region appears abnormally full. The most disparate types of femoral folds may indicate an incipient disease of the hip. There is normally no possibility of a displacement of the proximal end of the femur against the pelvis. Roentgen examination reveals that the caput femoris is abnormally small and that it stands apart from the acetabular fundus; the entire upper end of the femur is shifted up high against the region of the acetabulum (Y cartilage). The upper acetabular roof is steep. The earlier the diagnosis is established the more certain assurance of complete cure is vouchsafed, since all reduction maneuvers that have caused or might cause injury cease. Gocht recommends that the child patients' legs be kept in a spread position for some three months. In this way abnormal conditions are prevented and, in case an actual luxation exists, normal conditions of growth are again restored. In the discussion the physicians of the children's clinic pointed out that an asymmetry of the knee folds is a reliable early symptom, but this cannot be said of an asymmetry of the abductor folds.

Marriage Among Young Professional Men

At the suggestion of the expert advisers of the national ministry of the interior on matters of social and eugenic policy, a questionnaire survey of conditions among young professional men has been carried on in Saxony. Altogether 9,154 men submitted the filled-in blanks. Of these men 7,459 had completed their formal professional training. More than half of the men resided in the larger cities, the remainder in small provincial towns. Of the entire group, 57.4 per cent were unmarried. The most usual age at which the men married was the twenty-ninth year, whereas among the German population as a whole the most common age at time of marriage is 26. The peak of the birth rate for children of professional men also lay within the twenty-ninth year of the father's life. Of all young married professional men, that is, men under the age of 35, 51.9 per cent have no children. It is noteworthy that according to the information collected the thirty-fifth year was regarded as the crucial point of bachelorhood.

Early Recognition of Pulmonary Tuberculosis

A brochure for physicians on the early recognition of pulmonary tuberculosis has been published by the National Tuberculosis Committee. It ought not to be assumed, says the author, that a lung is free from tuberculous infection unless it has been so demonstrated by roentgen visualization. Therefore, roentgen examination should be made of (1) persons in whose ascendancy there has been a tuberculous taint or who have been exposed to tuberculosis; (2) persons who have been under a physician's care for a disorder of the respiratory sys-

tem (and of the larynx in particular) that has persisted beyond three weeks; (3) persons who within the past few years have had repeatedly to seek medical attention on account of "colds," acute bronchitis and similar disturbances; (4) persons who have suffered from an influenza, pneumonia or other disease of the respiratory organs, which has followed an atypical course; (5) persons who have suffered from a dry or a humid pleurisy (such patients should be observed over several years and subjected to periodic roentgen examination); (6) persons who cough up blood (not blood film in the mucus but liquid blood, even if only a few drops); (7) any patient who presents any other than pulmonary tuberculosis; (8) patients who present erythema nodosum and phlyctenae; (9) any patient who presents an anal fistula or a periproctical abscess; (10) all diabetic patients as well as all patients who present stubborn and obscure gastro-enteric disorders; (11) patients who suffer from an otitis media purulenta chronica the cause of which is not clear, and (12) patients who would be described as healthy but who complain of a symptom that might in any conceivable way be related to tuberculous infection.

BUENOS AIRES

(From Our Regular Correspondent)

March 1, 1937.

An Outbreak of Psittacosis

An outbreak of psittacosis recently occurred in Buenos Aires and the city of Tandil. The first patient came from Tandil to Buenos Aires for treatment, where he died after eighteen days. Some relatives and friends of the patient in Buenos Aires contracted the disease. Nine cases were reported, with two deaths. The physicians in charge of the cases made a tentative diagnosis of bronchopneumonia or infectious influenza and asked for laboratory tests. Professor Sordelli of the Instituto Bacteriológico of Buenos Aires made a bacteriologic diagnosis of psittacosis. The blood serum of five patients was sent to Dr. S. P. Bedson of the London Hospital at London, who found it intensely positive for the complement fixation test. No epidemic in birds at Tandil preceded the outbreak of psittacosis.

Trypanosomiasis

Cases of Trypanosomiasis cruzi in man have been reported in Argentina since 1924 by Muhlens, Zuccarini, Dios, Cyarzal and Salvador Mazza, who said that the infection followed a benign evolution and that the diagnosis was made accidentally during examination of the blood for malaria. Cecilio Romaña, however, reported fatal cases from Chaco of Santa Fe. Infection of the triatomas with Trypanosoma cruzi was verified in 1915 by Maggio and Rosenbusch. Trypanosoma infestation was found in 22 per cent of triatomas, which were included in a total number of 30,000 insects that were under examination for the infection. Trypanosomiasis in man, however, is rare. In the first three cases reported the parasites were found in the blood during examinations by the thick slide method in a total number of 15,000 blood samples. In 6,000 samples of human blood of persons living in Misiones the infection could not be found. The total number of cases of trypanosomiasis in man reported in Argentina is about seventy. White mice are more susceptible to the infection than any other animal. Dios and Vergreen in 1924 reported the results of inoculation with this infection in dementia paralytica patients who were inoculated with the blood of mice having experimental trypanosomiasis or with the blood of patients suffering from trypanosomiasis. The results of inoculation of trypanosomiasis in man were reported in 1924 by Muhlens and his collaborators in the *Revista del Instituto bacteriológico del departamento nacional de higien.* Trypanosoma cruzi was found in the blood of four out of seven persons who were inoculated by the subcutaneous route. The patients showed no definite symptoms of the infection. In some cases there was fever. The presence

of unilateral intense palpebral edema and conjunctival irritation found in some cases point, according to Romaña, to a conjunctival port of entry of the infection.

Pneumothorax Previous to Operation for Hydatid Cysts of Lung

Profs. Pedro Escudero, Ricardo Finochietto and José Arce advise the induction of artificial pneumothorax before doing an operation for hydatid cysts of the lung (*Semana méd.* 27:517 [Oct. 14] 1920). Since Professor Arce has given much attention to developing the method, it has been called by some writers the Arce method (Landivar, A. F.: *Semana méd.* 44:26 [Jan. 7] 1937). The subject was recently discussed before the Sociedad de Cirugía of Buenos Aires. Dr. Arce said that he has performed artificial pneumothorax as a preliminary step to operation in hydatid cyst of the lung in forty-two cases, with thirty-eight recoveries and four deaths. In thirty-three of the cases there was no infection. In thirty cases the recovery was uneventful.

New Faculty of Medicine

The structures now occupying the site of the new Faculty of Medicine were expropriated and will be demolished presently. The executive branch of the government has approved the project of constructing a nineteen story building at a cost of 12,000,000 pesos (\$3,140,000). The headquarters of the class rooms of histology and odontology were moved to private residences in order to leave a fourth part of the building of the faculty ready for the beginning of the construction of the building of the ministry of justice and public education.

Pan-American Medical Association

A branch of the Pan-American Medical Association was recently established in Buenos Aires with the board of directors made up of Drs. G. Araoz Alfaro president, José Arce vice president, Valls secretary, and Houssay, Zambrini, Puente and Saralegui directing members.

Personal Items

The following have been given the degree of doctor honoris causa: B. A. Houssay of São Paulo, P. Belou of Rio de Janeiro and J. Arce of Rio de Janeiro and of the Temple University of Philadelphia.

Dr. Camilo Muniagurria, professor of pediatrics at the Faculty of Medicine of Rosario and ex-president of the fifth National Congress of Medicine, is dead.

Marriages

SHELLEY RICE GAINES, Jacksonville, Fla., to Miss Claudia Norton Barret of Charlotte, N. C., in Clearwater, Fla., January 26.

JAMES SEARCY SNOW, Ann Arbor, Mich., to Miss Mary Farley Moody Boyles of New York, February 13.

DAVID BRYAN SLOAN to Miss Christine Katherine Futchs, both of Wilmington, N. C., February 6.

WILLIAM PATTON McDOWELL, Norfolk, Va., to Mrs. Loula Dean Rees, at Eufaula, Ala., January 23.

BERNARD GORDON SLIPAKOFF to Miss Miriam Harriet Kersline, both of Philadelphia, March 10.

JOHN ARTHUR SIEGLING to Miss Magdalen Keith Haskell, both of Charleston, S. C., March 10.

WILLARD F. GOFF to Miss Barbara Burwell, both of Seattle, at Port Blakely, January 17.

THOMAS SCOTT McDIARMID to Miss Audrey Dennison, both of Gadsden, Ala., January 31.

THOMAS J. STEWART to Miss Myrtle Tyer, both of Wynne, Ark., in December 1936.

FRED FALLS to Miss Anne Elmore, both of Lawndale, N. C., in February.

Deaths

David Alexander Stewart, Ninette, Manit., Canada; Manitoba Medical College, Winnipeg, 1906; member of the American Association for Thoracic Surgery and the American Clinical and Climatological Association; formerly associate professor of medicine (tuberculosis) at his alma mater; since 1910 member of the executive committee of the Canadian Tuberculosis Association and at one time its president; chairman of the public health committee, and past president of the Manitoba Medical Association; chairman of the committee of ethics of the Canadian Medical Association; superintendent of the Manitoba Sanatorium since its inception in 1908; in 1927 received the honorary degree of doctor of laws from the University of Manitoba, where he was a member of the board of governors; aged 63; died, February 16, at the Winnipeg (Manit.) General Hospital, of diverticulitis of the sigmoid.

Elbert Byron Swerdfefer, Denver; Denver Homeopathic College, 1904; practiced in Denver since 1904; member of the Colorado State Medical Society and the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; assistant professor of otolaryngology, University of Colorado School of Medicine; past president and vice president of the state board of medical examiners; served during the World War; aged 60; otolaryngologist to the Children's, Denver General, Colorado General and St. Luke's hospitals, Colorado Christian Home, and State Home for Dependent Children, and the Presbyterian Hospital, where he died, February 9.

Mark M. O'Meara @ Kingston, N. Y.; Albany Medical College, 1903; member of the Associated Anesthetists of the United States and Canada; fellow of the American College of Surgeons; past president of the Ulster County Medical Society; chief of staff and surgeon to the Benedictine Hospital; member of the associate surgical staff of the City of Kingston Hospital; consultant to the Ulster County Tuberculosis Hospital, Kingston, and the Veterans Administration Facility, Ellenville; consulting surgeon to the Memorial Hospital of Greene County, Catskill; aged 62; died, February 6, of nephritis and chronic endocarditis.

James Ernest Stokes @ Salisbury, N. C.; University of Maryland School of Medicine, Baltimore, 1892; member of the Southern Surgical Association and its vice president in 1917; fellow of the American College of Surgeons; served during the World War; chief of staff and secretary to the board of trustees of the Rowan Memorial Hospital, formerly known as the Whitehead-Stokes Sanatorium, which he owned and which was also known at one time as the Salisbury Hospital, where he was chief of staff; aged 64; died, February 1, of angina pectoris.

John Thomas Axtell @ Newton, Kan.; Bellevue Hospital Medical College, New York, 1883; in 1913 member of the House of Delegates of the American Medical Association; past president of the Kansas Medical Society; member of the board of education, and for many years a member of the state board of health; fellow of the American College of Surgeons; secretary and past president of the Kansas State Hospital Association; consulting surgeon to the Axtell Christian Hospital; aged 80; died, February 20, in Inglewood, Calif.

William Jackson Young @ Louisville, Ky.; Kentucky University Medical Department, Louisville, 1903; formerly clinical professor of dermatology and syphilology at the University of Louisville School of Medicine; fellow of the American College of Physicians; on the staffs of St. Joseph's Infirmary, St. Anthony's Hospital, Jewish Hospital, Norton Memorial Infirmary and the Kosair Crippled Children's Hospital; aged 55; died, February 7, of heart disease.

Charles James Wetherbee, Twin Falls, Idaho; Detroit College of Medicine, 1901; member of the Idaho State Medical Association, American Academy of Ophthalmology and Oto-Laryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; at one time mayor of Buhl; on the staff of the Twin Falls County General Hospital; aged 67; died, February 9, of coronary occlusion.

Frank Stanley Wasielewski @ Milwaukee; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; member and chairman of the board of trustees of the Johnston Emergency Hospital; member of the staff of St. Luke's Hospital; aged 62; died, February 3, in the Milwaukee Hospital, of carcinoma of the esophagus.

William Radcliffe Sitler, Suffern, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1875;

member of the Medical Society of the State of New York; health officer of the village of Suffern and town of Ramapo for many years; aged 83; died, February 5, in the Tuxedo Memorial Hospital, Tuxedo Park, of diabetes mellitus and cerebral hemorrhage.

Walter Scott Reed, Long Branch, N. J.; University and Bellevue Hospital Medical College, New York, 1900; also a druggist; formerly mayor of Long Branch, and member of the state legislature; for many years member of the board of education and school physician; on the staff of the Dr. E. C. Hazard Hospital; aged 72; died, February 28, of carcinoma of the prostate.

J. Swan Taylor, Johnstown, Pa.; Eclectic Medical Institute, Cincinnati, 1881; member of the Medical Society of the State of Pennsylvania; veteran of the Spanish-American War; for many years physician for the city schools, and physician and surgeon for the Pennsylvania Railroad; aged 78; died, February 12, of bronchopneumonia.

Amos Ellsworth Wyley Stueve, Cincinnati; Miami Medical College, 1909; member of the Ohio State Medical Association; on the staff of St. Francis Hospital for Incurables; for many years medical examiner for the Metropolitan Life Insurance Company; aged 51; died, February 16, of myocarditis.

Robert Pillow Jr. @ Columbia, Tenn.; Vanderbilt University School of Medicine, Nashville, 1914; past president of the Maury County Medical Society; on the staff of the King's Daughters' Hospital; health officer of Columbia; served during the World War; aged 50; died, February 13, of heart disease.

Henry B. Swartwout, Port Jervis, N. Y.; Bellevue Hospital Medical College, New York, 1885; member of the Medical Society of the State of New York; formerly mayor and president of the village; on the staff of St. Francis Hospital; aged 76; died, February 5, of myocarditis and influenza.

Samuel Lord Smith, Binghamton, N. Y.; State University of Iowa College of Medicine, Iowa City, 1882; member of the Medical Society of the State of New York; also a pharmacist; formerly city councilman and mayor of Binghamton; aged 78; died, February 15, of chronic myocarditis.

Reid Patterson, Charlotte, N. C.; North Carolina Medical College, Charlotte, 1912; member of the Medical Society of the State of North Carolina; on the staffs of the Mercy and St. Peter's hospitals; aged 48; died suddenly, February 16, in Atlanta, Ga., of coronary occlusion.

Joseph Rieger @ Dunkirk, N. Y.; Chicago Homeopathic Medical College, 1893; past president of the Chautauqua County Medical Society; member of the local board of health; on the staff of the Brooks Memorial Hospital; aged 71; died, February 4, of bronchopneumonia.

Abbott Revere Walker, Frostburg, Md.; Howard University College of Medicine, Washington, D. C., 1902; member of the Medical and Chirurgical Faculty of Maryland; was local health officer for many years; aged 66; died suddenly, February 1, of a cerebral hemorrhage.

Gustave Llewellyn Stoehr @ London Mills, Ill.; State University of Iowa College of Medicine, Iowa City, 1909; also a pharmacist; past president of the Fulton County Medical Society; aged 59; died, February 1, in the Methodist Hospital, Peoria, of pneumonia.

Seelye William Little, Rochester, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; author of a book entitled "Nephritis"; aged 69; died, February 27, of coronary occlusion and cerebral hemorrhage.

George Washington Russell, Waterbury, Conn.; Bellevue Hospital Medical College, New York, 1895; for many years president of the Waterbury Medical Association; aged 64; on the staff of St. Mary's Hospital, where he died, February 4, of pneumonia.

Thomas De Witte Peters, Flora, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; member of the Indiana State Medical Association; served during the World War; aged 51; died, February 11, of heart disease.

Ernst Zimmermann, Quincy, Ill.; Washington University School of Medicine, St. Louis, 1897; fellow of the American College of Surgeons; aged 60; on the staff of the Blessing Hospital, where he died, February 10, of cardiovascular renal disease.

James Bernard Hackley, Purcellville, Va.; University of the South Medical Department, Sewanee, Tenn., 1901; member of the Medical Society of Virginia; aged 60; died, February 4, in the Loudoun County Hospital, Leesburg, of mesenteric thrombosis.

Henry Burnham Savage, New York; Long Island College Hospital, Brooklyn, 1875; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1877; aged 83; died, February 1, in Fort Worth, Texas, of pneumonia.

Robert Freeman Oliver, Bradford, N. H.; University of Vermont College of Medicine, Burlington, 1890; member of the New Hampshire Medical Society; aged 74; died, February 5, of coronary thrombosis and chronic nephritis.

Frederick John Watson, Chicago; Rush Medical College, Chicago, 1893; member of the Illinois State Medical Society; aged 67; died, February 2, in the Presbyterian Hospital, following an operation for carcinoma of the colon.

Ralph Emerson Youmans @ Harrodsburg, Ky.; Kansas City (Mo.) University of Physicians and Surgeons, 1921; aged 39; died, February 15, at the Good Samaritan Hospital, Lexington, of renal calculus in solitary kidney.

Edward Arnold Schilz @ Grand Lodge, Mich.; Michigan College of Medicine and Surgery, Detroit, 1897; served during the World War; member of the state board of health; aged 64; died, February 1, of angina pectoris.

John Baston Acton, Eubank, Ky.; Louisville and Hospital Medical College, 1908; member of the Kentucky State Medical Association; formerly postmaster; aged 56; was found dead, February 26, of cerebral hemorrhage.

Phillip Henry Sigrist, New Philadelphia, Ohio; Cleveland Medical College, 1892; formerly school superintendent and county school examiner; aged 73; died, February 7, of arteriosclerosis and cerebral hemorrhage.

Helen Margaret Reinherr, Pittsburgh; University of Pittsburgh School of Medicine, 1935; aged 26; resident physician to the Allentown (Pa.) State Hospital, where she died, February 13, of acute cyanide poisoning.

Thomas Joseph Fenton, Spadra, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; aged 58; died, February 10, in Los Angeles, of Ludwig's angina.

William George Beattie, Tracy, Calif.; College of Physicians and Surgeons of San Francisco, 1900; aged 71; died, February 14, in the Dameron Hospital, Stockton, of chronic myocarditis and hypernephroma.

George F. Thomas, Peebles, Ohio; Medical College of Ohio, Cincinnati, 1888; member of the Ohio State Medical Association; for many years bank president; aged 80; died, February 20, of acute hepatitis.

D. Euclide Rainville, Boulder, Mont.; M.B., Laval University Faculty of Medicine, Quebec, 1888, and M.D., 1890; aged 71; died, February 28, of bilateral nephrolithiasis, acute urinary retention and uremia.

Charles Batty Small, Saratoga Springs, N. Y.; New York Homeopathic Medical College, 1883; formerly coroner, health officer and city physician; aged 76; died, February 7, of angina pectoris and arteriosclerosis.

Henry Harry Schiller, New York; New York Homeopathic Medical College and Flower Hospital, New York, 1935; aged 26; died, February 17, in the Mount Sinai Hospital, of sarcomatosis.

William Edgar Callison @ Winchester, Ind.; Yale University School of Medicine, New Haven, 1927; on the staff of the Randolph County Hospital; aged 37; died, February 26, of pneumonia.

Llewellyn Bert Raymond Smith @ Jeannette, Pa.; University of the City of New York Medical Department, 1895; aged 67; died, February 14, of myocarditis and interstitial nephritis.

Wilfred Elwell Pearce, Boynton, Okla.; Epworth College of Medicine, Oklahoma City, 1910; also a pharmacist; aged 59; died, February 17, in a hospital at Wichita, Kan., of arteriosclerosis.

Francis Michael O'Donnell, Newton, Mass.; Harvard University Medical School, Boston, 1887; member of the Massachusetts Medical Society; aged 73; died, February 10, of myocarditis.

Osmond Peter Thompson, Chicago; College of Medicine and Surgery, Chicago, 1909; aged 63; died, February 28, in the Illinois Masonic Hospital, of gastric ulcer and hemorrhage.

Henry Herbert Smith @ New Haven, Conn.; Jefferson Medical College of Philadelphia, 1877; aged 82; died, February 23, of arteriosclerosis and bronchopneumonia.

George Wilson Todd, New York; Columbia University College of Physicians and Surgeons, New York, 1901; aged 70; was found dead, February 20.

Bureau of Investigation

RE-DUCE-OIDS

Serious, and Even Fatal, Results Attributed to Reducing Nostrum by Physicians

During the past several years the Bureau of Investigation has received innumerable inquiries from physicians and laymen regarding a reducing nostrum euphemistically named "Re-Duce-Oids." A few examples follow:

An Illinois physician writes:

"I am seeking information about a nostrum which is known as Re-Duce-Oids, made by Scientific Laboratories of America and sold in Chicago by Walgreen drug stores. A young woman came into my office this morning with swollen, itching hands and felt very faint and dizzy after taking thirty-three out of a bottle of forty of these, according to directions . . ."

From an Indiana physician:

"Have you any information regarding Re-Duce-Oids? These are reducing capsules made by the Scientific Laboratories of America, San Francisco. Recently we had a post-mortem examination upon a patient

REDUCE-OIDS
Controllable FAT
"I LOST 55 lbs. of FAT"

writes Michigan Lady

Is fat making your life miserable? Many other women who used to sit back ashamed and uncomfortable because people laughed and called them "Fatty" have now found a new joy in living after freeing themselves from the burden and embarrassment of overweight. Don't let controllable FAT rob you of happiness!

READ WHAT THESE WOMEN WRITE:

Mrs. L. R. Schulze, 721 S. Pleasant St., Jackson, Miss.

Mrs. J. Fullis, Honey Creek, Iowa, writes: "Lost 34 lbs. RE-DUCE-OIDS are pleasant to take."

RE-DUCE-OIDS are not a new experiment—they have been used by thousands of fat people. Sold for 22 years. Pleasant, easy to take. **IMPORTANT—RE-DUCE-OIDS positively DO NOT contain dinitrophenol.**

FAT GOES...or Money Back

Get your money back in full if you are not delighted with the results you obtain from RE-DUCE-OIDS.

who was admitted with a very high temperature, convulsions, and a history of having taken an unknown quantity of these reducing capsules. She died a few hours after admission, and post-mortem examination revealed little except a marked degeneration of the heart muscle. Analysis of the liver, stomach contents and kidney was made for heavy metals and dinitrophenol. We have done several incomplete assays on some of the material that has been found in the reducing capsules, but as yet have been unable to connect the death of the patient with any of the material found. We hope that perhaps your department has done a complete assay and can give us information regarding the contents of these capsules."

From a Nebraska physician:

"I have just seen a patient who has been taking a popular reducing remedy with rather disastrous effects, and should like to know if you have investigated this substance and know anything about it. Whatever you can tell me will be appreciated. It is called Re-Duce-Oids. The effect suggests thyroid. There is nothing on the label to tell what it contains. It is very extensively advertised on the radio."

From a Michigan physician:

"Do you have information as to the ingredients of Re-Duce-Oid capsules, made by Scientific Laboratories of America? One of my obese patients took eight bottles of these over a period of a year, then became very weak and developed a pulse rate of 140-160, gradually became delirious and died. She had profuse sweats and for a time we thought she had developed an acute thyrotoxicosis."

From a New York chemical laboratory:

"We are wondering whether you have the analysis of the chemicals named Re-Duce-Oids, manufactured by the Scientific Laboratories of America. These capsules have been called to our attention by one of our physicians as causing eruptions and blotches on the skin of one of the patients. They were advised to take these pills for reducing by a pharmacist. It would lower the cost of my examination of these pills to the doctor if you have some information already on hand, therefore I would appreciate any cooperation that you may offer."

Re-Duce-Oids have been advertised to the public as an easy and pleasant method of removing excess weight. The copy has followed the usual stereotyped formula: a svelte female clad in step-ins and brassière, in what the copywriter no doubt considered a graceful pose calls attention to such slogans as "Reduce controllable fat," "Is fat making your life miserable? Many other women who used to sit back ashamed and uncomfortable because people laughed [they used to laugh when someone body or other sat down at the piano] and called them 'Fatty' have now found a new joy in living after freeing themselves from the burden and embarrassment of overweight. Don't let controllable fat rob you of happiness!"

The advertisements in periodicals were supplemented by pamphlets on "How to Reduce." In one such pamphlet put out by the Scientific Laboratories of America, 746 Sansome Street, San Francisco, the exploiter states:

"Re-Duce-Oids, in the true sense of the word, are not a medicine."

Just what constitutes a medicine in the true sense is not explained. Re-Duce-Oids are represented to the obese as

"a gland food put up in a capsule form . . . they provide a balanced food for the underfed glands which cause the fat condition."

Just which glands are provided with this "balanced food" is cleverly left to the reader's imagination. In addition to the periodical advertisements and pamphlets, the exploiter sent a form letter of the "Dear Friend" type to prospective purchasers.

Laughable indeed was the appeal:

"Do not accept any preparation in place of Re-Duce-Oids, for Re-Duce-Oids is the only reducing preparation that carries the certified Seal of Approval of the Scientific Laboratories of America."

for the American Medicinal Products, whose name appears on the trade package, is at the same address as the Scientific Laboratories of America—746 Sansome Street, San Francisco.

Once the victim has parted with his money for Re-Duce-Oids, he learns from the directions inside the trade package that

"we do not claim that Re-Duce-Oids will reduce everyone; they are intended for controllable fat."

The victim also learns that

"anyone having tuberculosis, diabetes or exophthalmic goiter"

should not take Re-Duce-Oids.

The exploiter also has a laxative pill to sell—"Alax"—which is recommended to Re-Duce-Oids users as a means of accomplishing the best results.

The A. M. A. Chemical Laboratory has recently examined a specimen of Re-Duce-Oids and reported as follows:

LABORATORY REPORT

"One original package of Re-Duce-Oids (American Medicinal Products, Inc., San Francisco, Calif.) was submitted by the Bureau of Investigation to the A. M. A. Chemical Laboratory for examination.

"Statements on the label were as follows:

40
Re-Duce-Oids
Capsules
See Directions Reverse side
Genuine
Price \$2.00

American Medicinal Products, Inc.
San Francisco, Calif.

"The directions given were to take one capsule daily for six days, then one capsule two times a day for six days, then one capsule three times a day with all following bottles.

"The package contained forty red-colored capsules which, with the contents, weighed approximately 0.35 Gm. each. The contents of each capsule averaged 0.3 Gm. Examination of the contents showed the presence of a yellowish amorphous substance possessing a slightly bitter taste, and color indicative of desiccated glandular substance.

"Qualitative tests indicated the presence of sodium, potassium, organic material, lactose, iodides, and small amounts of phenolphthalein and chlorides. Such substances as dinitrophenol, bladderwrack and starch were not found. Spectrographic analysis showed the presence of sodium, potassium, and a trace of calcium.

"The product was submitted for examination to a pharmacognosist, who reported the presence of protein and cellular material as desiccated glandular substance. Vegetable tissue was not found.

"The capsules apparently consisted of gelatin with a phthalein coloring material.

"Quantitative determinations on the powder yielded the following:

"Loss in weight (100 C.).....	5.14 per cent
Ash	1.74 " "
Sulfate ash	10.58 " "
Total iodine (I).....	13.2 " "
Potassium (K+)	3.64 " "
Sodium (Na+)	0.8 " "
Nitrogen (N)	2.08 " "
Reducing substances (as lactose).....	74.7 " "
Phenolphthalein	0.5 " "
Water insoluble material.....	11.97 " "

"From the foregoing, it is concluded that the product consists largely of desiccated glandular material, probably thyroid (approximately 12 per cent), potassium iodide (approximately 16 per cent) and phenolphthalein (approximately 0.5 per cent), with lactose as the excipient. This may be calculated to approximately 0.036 Gm. (0.55 grain) of glandular material; approximately 0.05 Gm. (0.77 grain) of potassium iodide; and approximately 0.0015 Gm. (0.023 grain) of phenolphthalein in the contents of each capsule. The dose after two weeks (three capsules a day) will contain approximately 0.11 Gm. (1.65 grains) of glandular material; approximately 0.15 Gm. (2.31 grains) of potassium iodide; and approximately 0.0045 Gm. (0.07 grain) of phenolphthalein."

Re-Duce-Oids, when stripped of the folderol of the enterprising copywriter, appears to be just another obesity nostrum depending essentially on thyroid, potassium iodide and a small amount of phenolphthalein. In addition, there is the usual nostrum trick of taking another product—one of the firm's proprietaries, to be sure—for insuring sufficient laxative action. The dangers of uncontrolled administration of such drugs have been mentioned repeatedly in these columns.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PURPURA HAEMORRHAGICA—COUNTING BLOOD PLATELETS

To the Editor:—I have had under my care a girl, aged 4, who suffers from what I have diagnosed purpura haemorrhagica. The clotting time is normal but the bleeding time is greatly prolonged. A wound will bleed for from twenty to thirty minutes. I have performed no platelet count as yet but intend to do so. The child has been given six direct blood transfusions to date. She has been given prescriptions for vitamins and iron and ammonium citrate in large doses. This child has been ill for five months. To date there has been no tendency to natural recovery. Is there any treatment that is worth trying except for the operative splenectomy? What method of blood platelet counting do you consider best for one who has not been accustomed to this method? Please omit name.

M.D., Idaho.

ANSWER.—There are a number of therapeutic measures besides splenectomy which have been used with apparent success in idiopathic purpura haemorrhagica. It is difficult to evaluate definitely the various methods of treatment because the disease is often characterized by spontaneous remissions of symptoms. In persistent cases, blood transfusions may be necessary not only for benefit of transfused platelets but also for relief of anemia. Intramuscular injection of whole blood or sterile human serum in 20 cc. amounts may result in a thrombocytosis and amelioration of symptoms. A high vitamin, protein and fat diet, along with liberal use of calcium orally or given intravenously and intramuscularly (10 cc. in 10 per cent solution) is advised for supportive treatment. Snake venom given intradermally, as advised by Peck, has been used successfully by Greenwald in children. The number of cases treated in this manner is too few to afford a basis for saying anything definite about the ultimate success of this form of therapy. Greenwald used diluted moccasin snake venom (obtainable through Lederle's Laboratories). The initial dose was 0.1 cc. of a 1:3,000 solution in physiologic solution of sodium chloride administered intradermally; this was gradually increased to 0.4 cc. in two cases and to 0.6 cc. in the third

case. The injections were given every other day at first and later every third or fourth day; the duration of the treatment varied from four weeks to five months. Active bleeding stopped in the three patients after the third or fourth injection.

Recently Rudisill gave a very optimistic report (*THE JOURNAL*, Dec. 26, 1936, p. 2119) on the successful treatment of essential thrombopenic purpura by the use of roentgen rays over the spleen. While the opinion as to the uniform success of this procedure is not shared by other investigators, it is worthy of trial. The following technic was advised by Rudisill: Voltage, 200 kilovolt peak; tube current 4 milliamperes; filter 0.5 mm. of copper plus 1 mm. of aluminum; roentgens per treatment 200 measured in air; roentgens per minute, 10; area exposed, anteriorly over the spleen; size of the field, 20 cm. circular.

It is important to remember that thrombocytopenic purpura may occasionally be a symptom of some other disorder, as leukemia, myelophthisic and aplastic anemias, infection, chemical poisoning or allergy (symptomatic purpura haemorrhagica). These should be ruled out.

One of the difficulties with platelet counting in clinical practice is that the more accurate and reliable methods are not sufficiently simple and the more simple methods are not sufficiently accurate and reliable. The one method that is relatively simple and avoids many of the inaccuracies common to a great many recommended is that of Olef (*J. Lab. & Clin. Med.* 20:416 [Feb.] 1935). His procedure is as follows:

The hand is immersed in warm water and opened and closed for exercise to produce active hyperemia and facilitate a rapid flow of blood when the finger is punctured. The palmar surface of the finger is cleansed with soap and water and dried with alcohol and ether or acetone. A puncture is made sufficiently deep to obtain a fairly free flow of blood without applying pressure. A drop or two of the blood is quickly wiped away. A drop of the diluting fluid is placed over the puncture wound before the blood reaches the surface of the skin and the hand is quickly turned palmar side down. After a sufficiently large drop has escaped, the entire mixture is applied to the surface of 3 or 4 drops of diluting fluid contained in a paraffin cup. A suitable cup is prepared by melting the center of a small cube of paraffin with the heated end of a glass rod. The contents of the cup are then stirred with a wooden applicator, the end of which is coated with paraffin. The mixture is allowed to stand for a minute or two, stirred again and then is transferred by means of a clean paraffin-coated applicator to a scrupulously clean glass slide in three drops. A carefully cleaned cover slip is placed over each drop and after the preparations have been allowed to stand for from ten to fifteen minutes a relative platelet count is made, the oil immersion lens being used. In such a preparation the platelets appear as clear, isolated, highly refractile bodies with numerous spinelike processes projecting from their periphery and are either motionless or exhibit brownian movement. The platelets and erythrocytes are both counted in fields taken at random in different parts of the preparation until 1,000 red cells have been seen. A red cell count is done in the usual manner, and the absolute number of platelets per cubic millimeter is determined. This is calculated from the following formula:

$$\frac{\text{Patient's red count}}{1,000} \times \text{number of platelets counted equals number of platelets in 1 cu. mm. of blood.}$$
 Normal counts range from about 400,000 to 600,000 by this method.

The author empirically found the following diluting fluid to be most satisfactory:

	Gm. or Cc.
Sodium metaphosphate (Howe and French, Boston)	1.0
Sodium chloride	0.5
Dextrose	0.1
Distilled water	100.0

Keep in a cold place.

If this solution is not available, other platelet counting solutions, such as 14 per cent magnesium sulfate, 2 per cent sodium citrate in 0.9 per cent sodium chloride, or the solution of Rees and Ecker may be used but the results are not quite as satisfactory.

PROTECTIVE MASKS AGAINST INDUSTRIAL POISONS

To the Editor:—Kindly advise me regarding an efficient mask to be worn by a worker in the dry cell battery manufacturing industry. The materials used in this industry are graphite, manganese and sal ammoniac.

J. R. LONDON, M.D., Passaic, N. J.

ANSWER.—No respirators worn by workmen are continuously efficient in the absence of intelligent servicing, fitting, and so on. It is believed that, among other respirators, those manufactured by Willson Products, Inc., of Reading, Pa. (No. 400 or

No. 400L) and the Mines Safety Appliance Company, Pittsburgh (No. C-R 8393), will prove to be suitable. Correspondence with either of these firms may be expected to provide exact information.

PURIFIED PROTEIN DERIVATIVE IN TUBERCULOSIS TESTING

To the Editor:—There has been some controversy among the physicians concerning the value of purified protein derivative for tuberculosis testing of school children. This is being used according to methods outlined by the Pennsylvania Tuberculosis Society. The positive reactions are all given physical examinations and the chests are roentgenographed. I should like to know the degree of accuracy and the value of such testing. I am anxious to get the best possible advice regarding this test, as through some of our physicians it has gotten into the columns of the daily newspapers and is creating considerable comment. I should like to have something definite from you so that I can present it at the next meeting of our county society and try to get it straight before the public. Please omit name.

M.D., Pennsylvania.

ANSWER.—Purified protein derivative, as well as old tuberculin, employed in the testing of school children, is a specific test for determining the presence of the primary tuberculosis complex in the child's body. The test is dependent on the fact that, when the primary complex is developing, the tissues of the body become sensitized to the protein of the tubercle bacillus. As long as the tubercle bacilli in the body remain alive, the sensitiveness of the tissues is maintained, and as long as this sensitiveness is present, tuberculin or purified protein derivative introduced into the layers of the skin results in a reaction at the site of administration which consists of an area of edema or induration, usually surrounded by an area of hyperemia. As far as is known, there is nothing in nature which is taken into the human body that is capable of sensitizing the tissues to tuberculo-protein except tubercle bacilli themselves. The bacilli of the bovine type will sensitize the tissues of the human body just as truly as those of the human type. The test therefore, is one for sensitization of the tissues, which is brought about by the presence of tubercle formation in the body. Therefore, the test is highly diagnostic of the presence of tubercles.

Not long ago it was said that approximately 90 per cent of the children of high school age had been infected with tubercle bacilli and therefore were positive reactors to the tuberculin test. However, in recent years through pasteurization of dairy products, eradication of tuberculosis among cattle herds, and isolation and treatment of large numbers of persons with tuberculosis in communicable form, infants and children have been so protected that large numbers of them have grown to adult life without becoming infected. Indeed, in many states less than 15 per cent of school children, including those of high school age, react positively to tuberculin. In Pennsylvania only about 20 per cent of the school children have been infected, except in certain sections of cities, such as Philadelphia. Obviously, therefore, the administration of the harmless and inexpensive tuberculin test almost immediately eliminates 80 per cent of the school children of Pennsylvania as far as further examination for tuberculosis is concerned. However, the fact that a child's tuberculin test is negative today does not necessarily mean that it will be negative in six months or a year; therefore, the 80 per cent who react negatively on first being tested should be retested annually as long as they remain negative.

When tubercle bacilli first find lodgment in the body, there usually develops what is known as a primary complex. This consists of the disease which develops at the site of lodgment, as well as that caused by bacilli carried from the original lesion by way of the lymphatics to the regional lymph nodes, where they are imprisoned.

The positive tuberculin reaction provides two significant facts concerning the individual, the first being that the positive reactor has at some time been in contact, either directly or indirectly, with a person or an animal suffering from tuberculosis or acting as a carrier or spreader of tubercle bacilli. This information is of extreme value, since many persons who transmit tubercle bacilli to others are not ill and the disease is not suspected. When a school child is found to react positively to the test, all the close associates should be carefully examined in an attempt to find the source. When this is done, not infrequently the healthy appearing individual in whom disease has never been suspected may be found to be the carrier. In such cases the disease at the source may not have advanced beyond the point at which it can be treated successfully. By finding such a case, therefore, a double service is rendered: First, the child may be protected against further exposure; second, the person with the communicable tuberculosis may be treated successfully in a reasonably short period of time.

The second fact of great value is that every child who reacts positively to the tuberculin test has or is developing the primary tuberculosis complex somewhere in the body. There is no particular advantage in searching for the location of this complex during life, for it is frequently located in parts of the body that do not lend themselves to special phases of the examination, such as the x-ray film. Moreover, the areas of disease which constitute the complex may not be sufficiently large so that the physical examination or the x-ray film will bring them to light. However, the fact has been well established that children who have the primary complex are far more likely to fall ill from clinical tuberculosis as adolescence approaches and thereafter than those who have not developed such a complex during childhood. Therefore, knowing through the positive tuberculin reaction that such a complex exists is sufficient reason to recommend that every child who reacts to the tuberculin test in a positive manner be most carefully examined, including the use of the x-ray film, as adolescence approaches, and if no clinical disease is detected the examination should be repeated at least annually. The fact has been reasonably well established that, after the reinfection or clinical type of tuberculosis has produced lesions sufficiently large to cast shadows which can be visualized on the x-ray film, there is a period of two or three years before symptoms appear. However, when symptoms do appear, approximately 80 per cent of such lesions are in the moderately or far advanced stage. They are not only disseminating tubercle bacilli but are difficult to treat successfully, whereas during the early stages of the disease, when it can be detected among positive tuberculin reactors by serial x-ray film examination, it may be treated successfully before bacilli are being disseminated to others and before symptoms make their appearance. The program in effect now in so many places, including Pennsylvania, consists, first, of administering the tuberculin test to as many school children as possible; second, seeking the sources or the persons who infected the children reacting positively and treating or isolating such persons; third, keeping all infected children under very close observation, including annual physical and x-ray film examinations, as the period of adolescence approaches and thereafter, and treating all who develop lesions of clinical significance at the earliest possible moment. This program, when carried to its logical conclusion, is more effective in tuberculosis control than any or all other methods combined.

WASSERMANN FASTNESS AND MARRIAGE IN SYPHILIS

To the Editor:—In March 1936, a woman, aged 24, single, was treated for intractable vomiting, lasting about three weeks, which was stopped by rectal administration of bromides and liquids. Physical examination revealed nothing of note, and a blood Wassermann test taken after recovery showed Kolmer's antigen strongly positive and the precipitin test definitely positive. Treatment was started with sodium bismuth thioglycollate, 3 grains (0.2 Gm.) twice weekly. Twelve injections of the latter were followed by eight intramuscular injections of sulfarsphenamine, each 0.3 Gm., following which a moderately severe exfoliative dermatitis occurred, clearing up on sodium thiosulfate. Neoarsphenamine could not be given because of small veins. Until the present the patient has had, in addition, ten intramuscular injections of bismuth salicylate at weekly intervals, four weeks of self-administered rest, followed by six weeks of mercury rubs with potassium iodide, and a second rest of six weeks. She returned, and now a Wassermann test by another laboratory shows the Noguchi antigen 2 plus and the cholesterinized antigen 3 plus. She feels well, has gained 10 pounds (4.5 Kg.) and shows no signs of involvement of the nervous or cardiovascular system. A spinal fluid examination has not been done because of unwillingness on the part of the patient. I plan to give her another twelve injections of sodium bismuth thioglycollate followed by six more weeks of mercury rubs and potassium iodide and then advise three courses a year of a bismuth compound with rest periods between for the next two years. Is this a case of a Wassermann-fast patient? When may this patient safely marry? Has treatment been adequate, excepting for a spinal fluid survey? M.D., Louisiana.

ANSWER:—It is too early in the treatment course to say whether this patient is going to be Wassermann fast, and the data obtained to date are not sufficient to warrant such a diagnosis. It is necessary to do a spinal fluid test, a cardiovascular examination and a careful neurologic examination before it may be said that she is Wassermann fast. The term "Wassermann fastness" has become popular because it apparently is an easy means of explaining to a patient why the blood test remains positive, at the same time being consoling to the physician. This is an unfortunate situation, because Wassermann fastness is not a diagnosis but merely an accumulation of serologic reports. The significant point about Wassermann fastness is that it may occur in any manifestation of syphilis, and it may have much significance or may be of no concern at all. For example, Wassermann fastness in a patient with early syphilis who has been well treated suggests that there is an active focus of syphilis somewhere, in either the nervous or the cardio-

vascular system, and that effort should be made to demonstrate it and treat it accordingly. Likewise, a persistently positive Wassermann reaction in association with a positive spinal fluid is indicative of a resistant type of infection in the nervous system. On the other hand, if a diagnosis of latency is warranted, and is confirmed by repeated examinations during the prolonged treatment course, the positive Wassermann reaction that has not been influenced by the treatment course may have no significance. The positive test does not necessarily mean that the syphilis is active or that the patient is infectious.

Accordingly, when Wassermann fastness is suspected, a careful search should be made for its explanation in the nervous system and viscera, and if active evidence of syphilis is found, treatment directed to the complication, perhaps of a special type, is indicated. However, if no complications are elicited, it is not necessary to continue to treat the positive serologic test indefinitely.

This patient should not marry until she has had a negative blood and spinal fluid test for three years after treatment has been stopped. If she marries and becomes pregnant, treatment for syphilis should be started early in the pregnancy even though the serologic tests are negative. The treatment as suggested should be carried out for the next three years.

SENSATIONS IN MOUTH AND NEUROSIS AFTER TOOTH EXTRACTION

To the Editor:—A man, aged 72, complained that about six weeks following extraction of all his teeth in 1930 his gums began to feel stiff and numb; his tongue felt large, especially after waking, and his mouth dry (he was unable to expectorate). He also complained of pains and prickly sensations in the arms and hands and the legs and feet, with swelling of the feet. The latter I have never seen. A prostatectomy for a benign growth of the prostate was followed by bladder irrigations with mild protein silver and an Indian oil (?) for a while. Both testicles were badly swollen in the hospital at that time but now one is hard and the size of a walnut, while the other is apparently normal. Last summer he took electrical treatment for the legs and feet, with no relief as I intimated to him, but early last fall I found he was taking barbituric acid derivatives, which I had him stop and at present he does not complain of painful extremities. He gives the legs and feet hot soaks at night now. Last summer artificial teeth were advised. After several months he stated that if he took the plates out his mouth felt numb and contracted, causing some difficulty in opening his mouth. When the plates are replaced, the mouth feels numb. His appetite is good. The abdomen is protuberant. The heart and lungs are essentially normal. He takes a laxative. The blood pressure in July 1935 was 180 systolic, and the hemoglobin from 85 to 90. In September 1936 his blood pressure was 140 systolic, 90 diastolic. September 11 he stated that his mouth felt sore all over, especially under the sides of the tongue just posterior to the frenum. On the upper and lower bony ridge where the plates fit there is numbness and the mouth seems dry. The mucous membrane is normal and moist but the tongue is slightly swollen and is red and furrowed. He states that he raises considerable stringy sputum in the morning. (Three or four years ago a throat specialist stated that the throat was normal.) If he awakens in the night he takes a few slices of orange with relief from the dryness, although he thinks he sleeps with his mouth closed. In the past, he has eaten cough drops and hard candy to increase the flow of saliva, but he uses very little now. Medication now is 5 grains (0.3 Gm.) of methenamine, two, three or four times a day, and Schlotterbeck's Mist. Helonin Comp., a desertspspoonful in hot water two or three times a day. One 1½ grain (0.1 Gm.) tablet of amylal is taken at bedtime. Urinalysis shows a specific gravity of 1.013, acidity, a trace of albumin, no sugar, a few small round cells, a small to moderate amount of pus, rarely a hyaline cast, and an occasional erythrocyte. Blood examination reveals hemoglobin from 80 to 85 per cent, white cells 11,250, red cells 5,000,250, polymorphonuclears 51 per cent, small lymphocytes 32 per cent, eosinophils 6 per cent, mononuclears 7 per cent, myelocytes 4 per cent, platelets normal, and red cells very slightly hypochromic. X-ray examination shows the maxilla and mandible normal. The patient does not use tobacco or alcohol. What would be your diagnosis and treatment for this man? Please omit name.

M.D., Massachusetts.

ANSWER:—In a man of his age who has undergone such a serious operation and who has taken so many drugs over a long period, a possible neurosis must be considered. Then, too, he may have some degenerative changes, which may account for the symptoms involving the fifth and ninth nerves, resulting from sclerotic changes in the cerebral vessels, affecting the nutrition of the nerve centers.

The feeling of numbness of the gums, especially the upper, may be due to pressure of the denture on the posterior palatine nerve and branches of the fifth nerve (especially the posterior part of the plate and the border of the plate as it extends upward into the sulci) or reflection of the mucous membrane over the cheeks and lip. Quite frequently vulcanite plates, which do not conduct heat, produce a congestion beneath them. This condition is often relieved by a metal plate.

The soreness at the sides and base of the tongue is quite common and quite baffling. Infection of the lingual tonsils and lymphatic tissue is at times thought to be the cause, but usually

when this tissue is operated on the symptoms are increased. At times, either natural or artificial teeth cause an irritation; such teeth should be ground and polished. Operative or strenuous medical treatment is contraindicated and general hygiene, change of scene and surroundings, with efforts to get him interested in some definite line of thought and effort, will tend to make him less susceptible to sensory disturbances and thereby he will be less disturbed by them.

He was probably subjected to too much shock during the extraction of all his teeth and recovery therefrom, and the ordeal probably has remained uppermost in his mind.

His blood examination reveals a slight anemia and his white count seems to point to an infection somewhere. If his temperature should be taken three times a day at regular intervals and recorded, it might help to clear the picture.

At any rate, a general line of treatment tending to get him up to par is indicated.

TESTS FOR ALCOHOL IN BLOOD

To the Editor:—I was wondering whether I could obtain any information concerning the micromethod of Widmark for testing the content of alcohol in the blood. A problem has arisen concerning drinking drivers following automobile accidents. I am at the present time police physician in Batavia, with a population of 20,000 people, and I should like to know more about this method and how it has worked out. I would appreciate it very much if you would tell me where I might obtain such information.

W. C. SWASEY, M.D., Batavia, N. Y.

ANSWER.—The Widmark method of testing for alcohol in the blood is described in the *Biochemische Zeitschrift* 131:473, 1922. This procedure is being used extensively in medicolegal cases in Europe and has the advantage of requiring only a few drops of blood.

It might be advisable also to consider other methods; namely, that of Nicloux (*Bull. Soc. chim. biol.* 13:857 [Sept.-Oct.] 1931 and 16:1314 [Sept.-Oct.] 1934) and of Friedemann (*J. Biol. Chem.* 115:47 [Aug.] 1936).

Another simple method has been successfully employed in more than 400 cases of drunken drivers in Pennsylvania alone and is now being used in several other states. The method depends on the change in color of potassium dichromate produced by alcohol. Permanent color standards corresponding to definite quantities of alcohol can be made or can be purchased from the LaMotte Chemical Company of Baltimore. Either blood or urine may be tested, but the urine is to be preferred because of the ease of collecting specimens for medicolegal purposes, and because the alcohol in the urine more nearly approximates the alcohol in the spinal fluid than does the alcohol in the blood.

The finding of alcohol sufficient to produce mental or physical inferiority is necessary for the scientific confirmation of obvious intoxication.

TREATMENT OF HAY FEVER BY APPLICATION OF ALCOHOL OR PHENOL TO NASAL MUCOUS MEMBRANE

To the Editor:—Will you kindly describe and briefly discuss the method of local desensitization of the nasal mucosa by injection of alcohol combined with phenol or by surface application of pure phenol as mentioned in *Queries and Minor Notes* in *THE JOURNAL*, Sept. 12, 1936. Please omit name.

M.D., District of Columbia.

ANSWER.—In 1933 H. H. Vail (*Arch. Otolaryng.* 18:651 [Nov.] 1933) described the method of treatment of hay fever by nasal injections of alcohol. He used a needle 1½ inches in length and inserted it 1 inch into the anterior half of the lower turbinate, withdrawing the needle slowly as he injected 2 cc. of solution. He then injected about 0.5 cc. in the septum; 2 cc. was injected in each side. The solution consists of 4 cc. of 40 per cent alcohol with 1 cc. of procaine hydrochloride 2 per cent without epinephrine. The injections were made beneath the mucosa after cocaineization of the site of injection. Rarely was it necessary to make an injection into the midturbinate, and the olfactory region was carefully avoided.

Vail reported twelve cases, three of "rose fever" (grass hay fever), with complete relief. In the other nine patients, all of whom had autumnal or ragweed hay fever, five obtained marked relief and four no relief. In one of the five successful cases two injections were necessary and in another one, while there was complete relief from hay fever, the asthma was so bad that the patient had to go north. This investigator states that the injections are not as painless as does Leichenring (*Ztschr. f. Hals-, Nasen- u. Ohrenh.* 28:220 [May 26] 1931). The patient gets severe shooting pains through the temple, cheeks, nose and teeth for about fifteen minutes, with gradual clearing within twenty-four hours. The bleeding is not severe but is annoying and may also last for about twenty-four hours. There

is extreme blanching of the mucosa. Vail strongly disapproves of the injection of alcohol in the sphenopalatine ganglion for hay fever or vasomotor rhinitis. He believes that the injections of alcohol are worth trying in cases of hay fever in which pollen therapy has been unsuccessful and in which it is not possible for the patient to seek a more suitable climate. The effect of a successful injection lasts from six to eight weeks. The greatest drawback is the severe pain.

Leichenring has had good results in 80 per cent of the cases and advises yearly injections. He asserts that there is but little pain.

The surface application of pure phenol may be carried out as follows:

The midnose is to be cocaineized with from 4 to 5 per cent cocaine for ten minutes; then pure phenol is applied by means of a warm applicator. The entire mucosa is swabbed up to just above the level of the midturbinate. The patient should be cautioned to avoid hawking up the material so as not to cause a phenol burn of the posterior part of the nose. Before this treatment is started it is well to smear the nasal margins with petrolatum in order to prevent a phenol burn. Following the treatment there is considerable local reaction, which lasts a day or two and then a cast of the membrane comes out. The results are good in some cases and the action is similar to that of ionization.

DESENSITIZATION IN DERMATITIS VENENATA

To the Editor:—June 6 I saw a white man about 35 years of age, a foundry worker, who had been suffering with dermatitis venenata on both hands since June 2. He had tried home remedies such as sugar of lead, epsom salt and potassium permanganate with no result. He was given a prescription containing boric acid, powdered zinc oxide, glycerin and witch hazel, which he used for a week with no results. As he was unable to do his work as a molder, poison ivy extract, a product of the U. S. Standard Products Company, was given every other day, starting with an intramuscular dose of 0.5 cc., which was increased to 0.75 cc. and on the third and last day to 1 cc. There was very rapid clearing and scaling of the lesions on both hands. As his hands cleared, however, he began to be troubled with burning and itching sensations about the torso and legs, particularly about the feet. At first there was a demonstrable lesion at the site of the burning. The first visible evidence of the urticarial lesion was about the eyes and in the hairy portion of the face. This was greatly aggravated by washing and shaving. This swelling about the face persisted intermittently for a week or ten days. Since July 1 he has been troubled with intermittent but daily urticarial lesions. He has been back at work with the exception of the first week and apparently has less difficulty with the urticaria when he is working in the foundry and perspiring freely, although the burning sensation is quite severe, particularly when the men are pouring the metal into the molds. When his case first became severe, epinephrine was used, with partial relief, in 8 drop doses over a period of four or five days. An attempt was made to let him carry on with ephedrine sulfate three-eighths grain (0.025 Gm.) and amylal 1½ grains (0.1 Gm.) because of the itching and burning at night, which prevented him from sleeping. After a period of a week this had no results. From the beginning he was placed on an alkaline diet with large amounts of fruit juice and soda, with small doses of magnesium sulfate in the mornings to aid in elimination. In addition he was given calcium gluconate 60 grains (4 Gm.) a day for a period of about three weeks, at which time it was increased to 120 grains (8 Gm.). At the time it was increased, parathyroid extract was given intramuscularly in 20 units every other day. At present, after a period of ten weeks, he has urticarial spots, principally on his back, face and arm, some of which are spontaneous in origin; others were produced after pressure. His forearms, feet and legs, back and shoulders are frequently the site of intense burning sensations. I have tried to list the treatment in the order of his calls. In addition, however, I have used bran baths, calamine lotion, salve containing menthol and phenol, minute doses of ergot, a milk diet and various treatments. X-ray treatment has been suggested for the skin but was not tried on recommendation of a very competent radiologist. If you can give me any help in this, I will appreciate it. Please omit name and state.

M.D.

ANSWER.—Although calcium was tried, it may not have been absorbed. Calcium gluconate could be given intravenously and, through the same needle, from 5 to 20 cc. of blood withdrawn and injected intramuscularly. The calcium can be given every other day, the blood injected every sixth day.

Ergotamine tartrate, 0.001 Gm. three times a day by mouth, may be given for not more than four days. It sometimes gives lasting relief.

Histamine is recommended for desensitization. Fiessinger and Gajdos use a 1:10,000 solution of histamine hydrochloride in water on the positive electrode of a galvanic current of from 6 to 10 milliamperes for five to ten minutes. The positive electrode is placed on the epigastrium, the negative electrode held in the hand. These treatments are given every other day and often relief is obtained in two weeks. The action of the electricity on the stomach is so slight that no untoward result may be feared (Fiessinger, N., and Gajdos, A.: *La reactogénotherapie de l'urticaire recidivante par l'ionisation a l'histamine*, *Presse méd.* 43:35, 1913).

Glaessner recommends aminoacetic acid, 10 Gm. or even 15 Gm. daily, dissolved in water or lemonade, given before meals. He believes that it has a detoxifying action. It is a diuretic but has no unpleasant action, even in large doses. He reports excellent results after eight or ten days of this treatment. (Glaessner, K.: *Die Wirkung des Glycocols auf Urticarielle Zustände*, *Klin. Wchnschr.* 6:597 [March 26] 1927).

The therapy of urticaria was described by Bernard Fantus and Theodore Cornbleet in *THE JOURNAL*, Aug. 24, 1935, page 595.

BURN OF EAR WITH POTASSIUM CYANIDE SOLUTION

To the Editor:—I have been taking care of a steel temperer who in February 1936 accidentally spattered a solution of 45 per cent potassium cyanide into his left ear. The temperature of the solution was 1,500 F. Burns of the skin of the external auditory canal and erosion of the tympanic membrane took place. As time went on, complete destruction of the drum and malleus and incus occurred. In order to prevent atresia of the canal, a catheter was inserted. At the present time there is a tendency for the external auditory canal to close down unless a catheter is kept in place. A large amount of granulation tissue is present in the middle ear, which recurs quickly even after cauterization with trichloroacetic acid and removal by the punch method. Of late the patient has complained of attacks of dizziness, headache and staggering. There are no signs of labyrinthine disturbance, although this must be present from the nature of the symptoms. There is almost complete loss of hearing in the affected ear. The roentgenograms taken from time to time show only slight clouding of the mastoid cells. I am contemplating doing a radical mastoid operation, because of the atresia of the canal and because of the granulations and symptoms of irritation of the labyrinth. Can you inform me of the nature of the activity of potassium cyanide on living tissue, especially that of the ear, and whether any cases of this type have been reported in the literature? What can you suggest for further treatment?

HAROLD LIEBERMAN, M.D., Worcester, Mass.

ANSWER.—The injury that took place to the patient's ear in all likelihood was not due to any specific action of potassium cyanide. What took place probably would have happened had any other liquid of the same temperature been involved. It appears (Chronic Potassium Cyanide Poisoning, *Queries and Minor Notes*, *THE JOURNAL*, Sept. 26, 1936, p. 1070) that the cyanides externally are, as a rule, without special effect. It is quite proper to consider the performance of a radical mastoid operation because of the obstinate atresia of the canal and the chronic otitis media, and because conservative measures have proved a failure so far. The patient has wholly lost his hearing on the affected side, so that operation will not increase his disability in this respect.

ANORECTAL SINUS

To the Editor:—I have under my care a married woman, aged 42, white, whom I first saw professionally one year ago, when she complained of a rectal discharge and pain of two months' duration in the region of the rectum and lower part of the back. Her past history, except for a miscarriage ten years ago after a five months period of gestation, is essentially negative. The patient is 5 feet 8 inches (173 cm.) tall, weighs 140 pounds (63.5 Kg.) and appears to be in perfect health. The general examination is negative. The Wassermann and Kahn reactions are negative. Digital examination of the rectum revealed a small, indurated tender area on the posterior wall about 1½ inches from the anorectal junction. Speculum examination showed a sinus opening from which pus flowed freely. A probe was inserted, which led into an irregularly shaped shallow cavity, measuring perhaps 1½ inches in each direction. In November 1935, under ether anesthesia with a speculum inserted in the rectum, the sinus was enlarged by incision, the cavity curetted, and a gauze pack inserted. Since operation the cavity has failed to heal in spite of several office treatments consisting of curetting the cavity and cauterizing it with 10 per cent silver nitrate solutions. The Koch bacillus could not be found in scrapings from the cavity. There is no pus in the cavity at present. It bleeds freely on the lightest probing. I should like to know what further treatment should be instituted in the case to facilitate complete healing. Would it be safe to let it go entirely for a period of several months to see whether healing would occur? If published, please omit name.

M.D., Illinois.

ANSWER.—Any lesion at the anorectal outlet which fails to heal in a reasonable length of time, when properly cared for, should be regarded with suspicion. The tissues that were removed at the first operation should be sectioned and examined microscopically. If this is not possible, fresh tissue should be taken and subjected to careful microscopic examination. If the lesion involves a portion of the lower part of the rectum, as well as the anus, it may be an adenocarcinoma. If only the anus is involved, it is probably a squamous cell epithelioma. The latter is very malignant, and although it may disappear readily following radium treatment, the ultimate prognosis is very grave.

If the physician is dealing with an anal abscess that has originated as a simple infection of the anal crypts, he should be able to produce permanent closure by dissecting out the walls of the abscess and allowing the wound to fill in by granulation. Such a wound should be opened well at its

external margins so that drainage will not be interrupted, and although it is necessary to pack such a wound immediately after operation, the gauze should be removed within forty-eight to seventy-two hours and in its place light dressings, saturated with medicated solutions, should be substituted. The rectum should be irrigated following each evacuation of the bowel, and the wound should be dressed daily until it is entirely healed.

LOW CHOLESTEROL DIET

To the Editor:—I wish to have outlined a low cholesterol diet. Also, has there yet any literature accumulated on the influence of a high blood cholesterol on Wassermann fastness? P. J. DELANO, M.D., Chicago.

ANSWER.—Unfortunately the amount of work done in the field of investigation of the cholesterol content of foods has been relatively meager. The greatest dearth exists in the analyses of food products as eaten. This inadequacy renders an accurate prescription of a low cholesterol diet subject to much criticism.

Gleaned from the analyses available, a diet can be compounded by respecting the following two lists:

Foods Highest in Cholesterol*

Brains †	Liver †	Lard
Egg yolk †	Sweetbreads †	Meats and poultry
Fish roe †	Butter	Oysters
Kidney †	Fish	Suet

Foods Lowest (Negligible) in Cholesterol*

Breadstuffs	Nuts
Egg white	Sugars and syrups
Cereals	Vegetables
Fruits	Vegetable oils

* From Bridges, M. A.: *Dietetics for the Clinician*, ed. 3, Philadelphia, Lea & Febiger, 1937.

† Outstanding.

A casual survey of the literature fails to reveal any material on the relation of high blood cholesterol and Wassermann fastness.

HYDROCEPHALUS

To the Editor:—An infant, aged 3 months, has hydrocephalus, which was first observed three weeks after a normal delivery. The infant had, however, a spina bifida. There has been quite constant drainage from birth, but this is now quite completely healed over with epithelium. The baby's head since the first observation increased rapidly in size and circumference, in all ways giving the usual picture. At about 2 months of age the hydrocephalus seemed to be abating, but with increase in the amount of discharge from the lumbar spinal lesion. This was quite marked for almost a week, but as the spinal lesion healed over and there was little or no drainage, the head again is becoming more tense, although not enlarging much. Outside of a somewhat incomplete flaccid paralysis of the lower extremities (they are not developing with the rest of the body), there is little else in the way of paralysis. The bowels and bladder are under control. The baby eats, sleeps and seems to be gaining fairly well, although the stomach capacity seems not to exceed 3 ounces (90 cc.) of milk at a feeding. Can or should anything be done as to the hydrocephalus and the spinal lesion? If so, when? If the spinal lesion does not discharge more, and the hydrocephalus continues, should a lumbar tap or ventricular puncture be done (of course, by one competent)? What are the results of such treatment? Should physical therapeutic measures and position (molded splints) be carried out as in other cases of flaccid paralysis? What is the prognosis if one stands by, as is so often advised? The parents are resigned to what fate I have been able to inform them. Incidentally, they have other normal children and this one came many years (ten or so) after the preceding one. Please omit name and town.

M.D., Iowa.

ANSWER.—In any case of hydrocephalus it should be remembered that spontaneous arrest may occur at almost any stage of the development of the condition. If spontaneous arrest occurs at an early stage there may remain only a moderate enlargement of the head and no limitation of intelligence. The question of what to do and when to do it is difficult to answer in any given case. It is known that hydrocephalus not infrequently develops following a successful operation for spina bifida. Therefore, in the case in question, should an operation for removal of the spina bifida be successful, the hydrocephalic condition would probably be aggravated. Surgical treatment of the hydrocephalus would probably consist in an attempt to remove part of the choroid plexus, thus diminishing the source of the cerebrospinal fluid. Such an operation is a dangerous procedure and the mortality is high.

In cases of hydrocephalus combined with spina bifida, ventricular puncture would be the site of choice for draining the cerebrospinal fluid. The benefit of such drainage would be only temporary and each instrumentation would carry with it considerable danger of infection. The flaccid paralysis might be helped by simple splints. Any prognosis in such a case must be extremely guarded. When the condition develops

after birth and progresses rapidly, a fatal outcome usually occurs before the end of the first year. If measurements of the head are made at given intervals and the increase in circumference spontaneously ceases, a better prognosis is indicated. Such an arrest of the hydrocephalus is thought to be brought about by a diminution in the production of cerebrospinal fluid, so that an equilibrium with absorption by the meninges has taken place. In the case in question a watchful attitude rather than surgical intervention would seem the wiser course, in the hope that spontaneous arrest may occur before too great damage to the brain substance has been done.

TOXICITY OF CHROMATES

To the Editor:—A man, aged 45, has been working with dyes in an industrial plant for ten years. For the past nine years he has been troubled with what he calls boils of his neck, face and hands. Examination reveals an extensive but superficial induration with ulceration and purulent discharge on a large area of the back of his neck, with smaller patches on his face and hands. These have shown rapid improvement in a week's time with a simple soothing ointment and keeping the lesions covered while working. I am presuming there is some irritation to which he is exposed while at work. There have never been any lesions on part of his body covered by clothing. Patch tests were done with the various dyes that he has been using. Pyrogallol acid showed a marked skin reaction and potassium bichromate a mild one. The others were all negative. This man does the actual heating and mixing of the dyes. Would it be likely that the fumes of the pyrogallol acid cause skin irritation followed by secondary infection? As I believe that potassium bichromate is nonirritating, could he have developed a sensitivity to this substance which might be a causative factor? Could you make any recommendations for future prevention, as it is not practical for him to change his occupation? Please omit name if published.

M.D., New York.

ANSWER:—Contrary to the opinion expressed in this query, solutions of potassium bichromate are directly irritating both to the broken and to the unbroken skin. However, "chrome holes" seldom become secondarily infected. Chromates and chromic acid are hydrolyzed with such difficulty that some bactericidal action long remains at the site of local injury. As suggested in the query, a few workers become sensitized to the action of chromic acid and its compounds. Patch tests, unless made with high dilutions of chromium compounds or chromic acid, will provide an apparent positive reaction as a result of direct irritation. Almost all dye workers are exposed to a variety of skin irritants. It is believable that if the described disorder is in truth the result of work exposure, mixed irritants probably are responsible rather than any one specific dye or other chemical present. Conditions are made worse by high temperatures. The pyrogallol acid is a skin irritant, but it is not believable that full responsibility can be placed on this one substance. In fact, due consideration should be given to the possibility that this workman, like hundreds of others, suffers from a furunculosis, unrelated to work as the cause. An extensive discussion of skin irritating dyes may be found in the publications of Schwartz of the United States Public Health Service.

RECURRENT NASAL POLYPS

To the Editor:—A patient of mine, a boy aged 17 years, has been operated on sixteen times in five years for nasal polyps, which always have recurred on the same site of the nose. He has been seen and treated by many a specialist in the field and nobody seems to know of any possible way to avoid such recurrences. The last surgeon spoke of some allergic studies of the case, but as far as family history, life and occupation of the patient go there is no hint of any possible allergy. I heard sometime ago of some operation to reline, so to speak, the nasal passages with some artificial membrane, transplant or grafting, but I did not read anything about it in any medical paper. I would appreciate information or suggestion about the most recent radical treatment for nasal polyps. Kindly omit my name.

M.D., New York.

ANSWER:—The situation described is common in the experience of every rhinologist. One cannot determine in every case what the underlying reason is for the presence of polyps, and hence for their recurrence. Complete studies to determine idiosyncrasy to foods, inhalants and other irritants should be made but are often disappointing. Apart from this, the fact that polyps recur is no reason for becoming unnecessarily despondent. A few polyps at a sitting may be removed in the office to give relief for weeks or months. If the patient is able to breathe freely through his nose, the presence of a few small polyps cannot possibly harm him.

Neither irradiation nor operation nor relining the nasal passages with artificial membrane, transplanting or grafting (the last suggestion is not familiar to us) can hold out promise of total relief. Removing the polyps as completely as possible and using radium locally has been highly recommended. Best of all, perhaps, if recurrences are frequent and troubling, would

be an external operation on the ethmoids and antrums, if they are involved, with widespread removal, under direct inspection, of the diseased mucous membrane. Even this, in the hands of the best men, has been found disappointing on occasion.

INFECTION AND CARBOHYDRATE TOLERANCE IN PERSONS WITH DIABETES

To the Editor:—I am a diabetic patient, with blood sugar down from 266 to 214. I am mentally clear, feel better, and had a carbuncle excised one week ago. Will the blood sugar and urinary sugar (I am getting 20 units of insulin) go away or will it stay high until the carbuncle is healed? I am mentally clearer and that should be a good criterion. Please omit name.

M.D., Illinois.

ANSWER:—Infection almost invariably decreases carbohydrate tolerance in diabetic persons and renders the administered insulin less effective. It is good practice, therefore, to increase the amount of insulin given to a diabetic patient who is suffering from an infection until the glycosuria disappears and the blood sugar hovers about the normal range. As the infection clears up, the insulin should be progressively reduced as warranted by the decreasing diabetic manifestations. Hence it would be wise not to wait for the healing of the carbuncle to allow the hyperglycemia and glycosuria to improve. However, if one did wait, the time at which improvement in tolerance would occur depends more on the time at which absorption of toxic products from the carbuncle ceased than on the complete healing of a clean granulating area.

THRESHOLD OF IRRITABILITY—USE OF HYDROCHLORIC ACID IN PERSISTENT DERMATITIS

To the Editor:—In the Sept. 12, 1936, issue of THE JOURNAL, in answer to a question captioned "Persistent Dermatitis" (p. 899), mention is made in the last paragraph of giving calcium lactate with lactose and diluted hydrochloric acid. Would you kindly explain: 1. What is meant by the "threshold of irritability" and the reason for giving calcium lactate and lactose? 2. Why is hydrochloric acid given? Please omit name.

M.D., New York.

ANSWER:—1. The threshold of irritability is the barrier that prevents a latent irritability from becoming manifest. When this barrier is lowered by any cause such as overwork, dissipation or infection, the susceptible tissue shows the evidence of irritation. When the threshold is raised again by rest, physical or mental hygiene or in any other way, the symptoms of irritation subside and the irritability becomes latent. Calcium is given to increase the cell content of this metal, which causes the cell to become less easily irritated. The lactose during digestion releases lactic acid, which aids the absorption of calcium.

2. Hydrochloric acid decreases the alkalinity of the organism and aids the absorption of calcium.

PRENATAL SYPHILIS

To the Editor:—I am interested in an evaluation of the prospects for good health, fecundity and healthy offspring of a man, aged 24, with congenital syphilis who contemplates matrimony. The patient first came under my supervision when 21 years old, suffering from an ulnar bursitis. He had Hutchinson's teeth and a two plus blood Wassermann reaction, but no other recognized stigmas. There is a presumptive history of maternal prenatal syphilitic infection, untreated before or during pregnancy. The patient is the only offspring. There is no history of postnatal syphilitic lesions or treatment, and the pegged teeth were the only clues present before the bursitis developed. The bursitis promptly disappeared when injections of neoarsphenamine were begun. Thirteen injections of 0.4 Gm. were given, as well as nine injections of 0.2 Gm. of sodium bismuth thioglycollate. The Wassermann reaction was unchanged but the patient did not submit to further treatment until two years later, when he developed a depression neurosis. Then seven injections of tryparsamide 2 Gm. were given, and again there was marked improvement in his condition. Six months later there was a severe gastroenteritis with jaundice and marked bilirubin, after some twenty tablets of a "patent" medicine (Brom-Quinine) were ingested in one day's time for a respiratory infection. The jaundice cleared up in one week with palliative treatment. The treatment has been, admittedly, inadequate; the stubborn Wassermann reaction does not concern me so much as the fear that the patient may be unfit for marriage from the eugenic and economic standpoints. Kindly omit name, city and state.

M.D.

ANSWER:—The patient is undoubtedly suffering from prenatal syphilis. His treatment is inadequate and one cannot say, even at the age of 24, that he is free from risk of such a serious complication, for example, as severe keratitis or perhaps a keratitis of both eyes. Moreover, the symptoms mentioned—a depression neurosis—may well be beginning dementia paralytica. It is unfortunate that a lumbar puncture has not been done on the patient as yet, and this should be carried out at once. A cell count, globulin test, gold colloid

curve and Wassermann test should be done on the spinal fluid. Certainly until this is done the matter of marriage must be absolutely set aside.

If the lumbar puncture is negative, the patient should have continuous therapy for one year of alternating courses of an arsenical and of a bismuth compound; for example, using neoarsphenamine or mapharsen in weekly doses for a series of ten injections, following this with weekly injections of bismuth salicylate 0.2 Gm. for a series of ten injections, giving two courses of the arsenicals and two of the bismuth. Along with it potassium iodide should be exhibited.

The blood Wassermann reaction in itself will probably be difficult to change to negative and does not have so much moment as the possibility of the involvement of the central nervous system. Certainly if the spinal fluid is positive in this case there should be consultation with some authority in this field before any more consideration is given to the matter of marriage.

PELOUZE TREATMENT OF GONORRHEA

To the Editor.—In reply to a reader's question as to Pelouze's treatment of gonorrhea in the March 20 issue of THE JOURNAL, the answer is substantially an abstract of one of Pelouze's chapters from his textbook. The reader is informed that in acute anterior urethritis strict adherence to anterior irrigations with permanganate solution 1:8,000 and instillations of a few cubic centimeters of a weak solution of mild protein silver bring about cure for 90 per cent of cases in six weeks and that 10 per cent require from one to three weeks' additional treatment. Pelouze is also quoted to the effect that from 75 to 85 per cent of the cooperative patients seen before the fifth day fail to have a posterior extension of the disease. While such results are devoutly hoped for, alike by patient and by physician, claims for six weeks cures from this routine are misleading and in actual practice seldom duplicated by others. It is wise to tread cautiously regarding the following advice from the textbook: "For posterior urethritis, in acute posterior urethral infection oral sedatives are given and all local treatment, except hot hip baths, is stopped until about a week after the patient has regained his bladder comfort. Then low pressure (not more than 3 feet) hydrostatic irrigations of 1:8,000 potassium permanganate are given into the bladder (no catheters or other urethral instruments are ever passed until it is safe to assume the gonococcus no longer is present). The bladder is only partially filled, the patient voids and this is repeated several times, some of the solution being left in the bladder at the end of the treatment. Treatments of this type are carried out two or three times a week." Those inexperienced had better avoid this type of treatment. Experienced urologists mostly avoid this type of treatment, so as not to encourage persistent prostatitis and vesiculitis and the likelihood of an acute, disabling epididymitis.

MAURICE MELTZER, M.D., New York.

PNEUMOCOCCIC MENINGITIS

To the Editor.—In Queries and Minor Notes in THE JOURNAL March 27, page 1136, you answer questions with regard to a case of pneumococcic meningitis. Although I am only a laboratory technician, I feel that I must criticize a part of your reply. To begin with, I have seen a patient with pneumococcic meningitis recover and am told that there are others in the literature. These are not just diagnosed as gram-positive diplococci but typed by the Neufeld method. The case I referred to was type XII pneumococcus from the spinal fluid. Then too I do not think you should advise pneumococcus antiserum without definitely stating that only after the type of pneumococci has been determined should the homologous type of therapeutic serum be administered. Pneumococcus curative serum is of value only when one has the same type serum available as the invading organism.

F. A. SENIOR, Department of Internal Medicine, Cincinnati General Hospital, Cincinnati.

"PROPER MANOMETRIC READINGS IN ARTIFICIAL PNEUMOTHORAX"

To the Editor.—In THE JOURNAL, March 6, I noticed that there was a request for information on the proper manometric readings in artificial pneumothorax. The answer to this question goes into some detail with regard to the use of pressure in artificial pneumothorax but I believe has entirely missed the real question. I believe the question was directed as to the correct readings in use today, that is, whether to be read as shown on the average manometer or whether to be doubled. In the article by Peters and others in the November issue of the *American Review of Tuberculosis*, there is considerable discussion on the proper pressures to use.

OSCAR LOTZ, M.D., Milwaukee.

INHERITANCE OF HEMOPHILIA—A LITERARY ERROR

To the Editor.—I thought you might be interested in what is apparently an error in medical knowledge displayed by Housman in his "Victoria Regina." In it he states that Victoria's husband, Albert, did not inherit the family strain of hemophilia because his mother had been indiscreet and his own father was not the king of Saxe-Coburg Gotha. The latter was apparently the hemophilic line. All the references I can find state that hemophilia is transmitted only through the female, and I would judge from that that the male offspring of a hemophilic father would be free unless the mother was also of hemophilic heredity.

J. R. RODGER, M.D., Bellaire, Mich.

Book Notices

Thirty-Fourth Annual Report, 1935-1936, of the Imperial Cancer Research Fund Under the Direction of the Royal College of Physicians of London and the Royal College of Surgeons of England. Paper. Pp. 43. London: The Fund, 1936.

This report of the director of the Imperial Cancer Research Fund, W. H. Gye, reflects again the many activities of the institution, which embrace cancer research in almost all its phases. Although many important confirmations have been made through the experimental work of the past year, no epochal results are found in this report. The main chapters to which contributions have been made during this period by the staff of the Imperial Cancer Research Fund are on carcinogenesis, on viruses, and on the study of the effect of radiation on the physiology of cancer tissues.

In the introduction to the report of the work on carcinogenesis, Gye tries to give this factor its proper place in the conception of cancer etiology, according to his well known ideas. It is again emphasized that the etiology of cancer presents two entirely different and mainly independent aspects: (1) the intrinsic cellular change that confers on a cell the property of malignancy (here called the proximate cause of cancer) and (2) the conditions acting from without on a normal cell that produce the "precancerous conditions of the tissues" (remote causes of cancer). According to this conception the latter prepare the area of tissue for the intrinsic cellular change by which a malignant cell is formed from a normal cell. The underlying assumption that the factors which confer on a normal cell the property of continuous and autonomous growth reside within the cell is stressed again in a paper by Cramer, Cancer in Man in the Light of Experimental Cancer Research.

The research on carcinogenic agents conducted during this year is particularly concentrated on the effect of radioactive substances and of hormones. The first phase is represented by the studies of Selbie, who confirmed former experiences of other authors of the carcinogenic power of thorium dioxide. The production of sarcomas, even with small amounts of thorium dioxide, indicates the danger of this agent if introduced into the human body.

The studies by Cramer and Horning regarding the carcinogenic power of estrogen have confirmed the experiments by Lacassagne in producing mammary cancer in male mice by this agent. They have furthermore demonstrated that painting of the skin with this agent also produced mammary cancer but not cancer of the skin, which indicates an organ specificity for these carcinogenic agents.

Besides the carcinogenic effect of estrogen, the application of this substance has given rise to very characteristic changes in other endocrine organs (increase in size of the islands of Langerhans in the pancreas, degenerative changes in the adrenals, changes in the pituitary gland which might proceed to the formation of adenomas of the anterior part). The clinical symptoms in the animals which have shown these changes resemble closely those observed after surgical removal of the pituitary gland, so much so that Gye states that "the prolonged application of certain oestrogenic hormones produces a functional hypophysectomy which morphologically is associated with an enlargement of the anterior part and a loss of its chromophil cells."

With regard to the carcinogenic power of estrogen, it is particularly stressed that there is no danger in the clinical application of these substances, since the dose therapeutically administered is too low.

In another line of investigation Cramer demonstrated the contrast between the susceptibility to mammary cancer and tar-induced cancer of the skin which, under certain conditions, even exclude each other. This therefore does not afford support to the belief of the existence of a general susceptibility to cancer. The observation that in animals with active mammary cancer the production of skin cancer by tar painting is very difficult indicates that the effect of a carcinogenic agent is conditioned by systemic factors, although in itself a localized process.

In the field of research on viruses in relation to cancer, two phases have been under examination. McIntosh had previously reported the successful transmission of tar tumors in fowls by cell-free filtrates. Foulds has repeated these experiments but could not reproduce the results. His experiments of transmitting dibenzanthracene tumors by cell-free filtrates out of these tumors failed. He could, however, immunize rabbits by injection of tissue of an avian dibenzanthracene tumor, as well as by the injection of cell-free extracts from these tumors. Both these injections produced antibodies in the blood of the immunized rabbits which had the power to neutralize the virus of the Rous sarcoma.

The other line of investigation concerning viruses is the study of rabbit papillomas by Selbie. This study demonstrates the surprising fact that it is possible to induce tumors by injection of cell-free filtrates of the benign papilloma but that the supposed virus disappears if the tumor changes into a malignant one.

In the field of the effect of radiation therapy, Crabtree has continued his studies on the effect of radiation of the respiratory and glycolytic systems on the cells. There is a selective action on certain specific cell mechanisms which are affected independently of one another. Tissues irradiated by body temperature slowly lose their respiratory power, whereas the glycolysis remains unaffected. Tissues cooled at 10 degrees or less show first the detrimental effect on glycolysis while respiration still remains unimpaired. Crabtree showed furthermore that the enzyme glyoxalase remains unaffected through radiation, even when the total glycolysis of the tumor is considerably reduced. This is important for the support of the theory in which glyoxalase plays no part in the transformation of sugars into lactic acid.

In Cramer's studies of irradiation of malignant cells with sublethal doses of radium, he could not produce an artificial radioresistance. The repeated transplantation and irradiation with sublethal doses showed a gradual decrease in the rate of successful inoculations, indicating that the effects of small doses of radiation are cumulative and that the period of recovery from slight damage is longer than has been assumed.

Transplantation studies by Selbie with two mouse tumors showed the factor of natural resistance to transplantation to be hereditary. This again supports the classic experiments of Little, Strong and Bittner in this country.

Georg Wilhelm Steller: *The Pioneer of Alaskan Natural History*. By Leonhard Stejneger. Cloth. Price, \$6. Pp. 623, with 31 illustrations. Cambridge, Mass.: Harvard University Press, 1936.

The subject of this biography was a physician, who was one of the greatest naturalist explorers in Alaska and a member of the expedition which in 1741 discovered Alaska for the Russian government. The author of the book followed Steller's course, checking over his observations and collecting a mass of material from Steller's own writings and from contemporary publications, on which this biography is based. The result is

a volume full of interesting revelations and most fascinating for all who have ever visited Alaska. It reveals the hardships of the early explorers in that territory and provides an account not only of Steller's work but also of the investigations made by the great Bering, whose name is indelibly associated with Alaskan geography. The book is beautifully illustrated with many colored plates, maps and charts. There are some medical references of special interest, and a series of appendixes of particular importance to naturalists. The bibliography is profound and an indication of the scholarly character of the work.

Die gynäkologischen Operationen und ihre topographisch-anatomischen Grundlagen. Von Prof. Dr. med. Heinrich Martius, Direktor der Universitäts-Frauenklinik, Göttingen. Paper. Price, 52 marks. Pp. 396, with 404 illustrations. Leipzig: Georg Thieme, 1937.

This ranks foremost as an operative gynecology. All gynecologic operations plus appendectomy, herniotomy and ureteral transplantation are described in detail. Particularly gratifying are the detailed descriptions of plastic operations and the intra-abdominal operations of round ligament shortening and sterilization as done by the vaginal route. The text is profusely illustrated with drawings and diagrams that in themselves are so well done that the knowledge of German is hardly necessary for a complete understanding of the anatomy and technic employed in the completion of the operations. Not only are the surgical procedures well illustrated, but every operation is described in an anatomic diagram showing the relationships between all the organs that may be encountered. This book can be recommended without reserve to all gynecologists, general surgeons who may encounter pelvic disturbances, and postgraduate students who are interested in learning gynecologic technic and anatomy. The diagrammatic drawings are of the best and in themselves provide a perfect textbook of gynecologic anatomy. The volume should be a part of the library of every physician who has occasion to invade the female pelvis for surgery.

Surgical Diseases and Injuries of the Genito-Urinary Organs. By Sir John Thomson-Walker, D.L., M.B., C.M., Consulting Urologist, King's College Hospital. Edited by Kenneth Walker, M.A., M.B., B.C., Lecturer in Venereal Diseases, St. Bartholomew's Hospital. Second edition. Cloth. Price, \$10. Pp. 974, with 341 illustrations. Baltimore: William Wood & Company, 1936.

In this excellent treatise on diseases of the genito-urinary organs, the high standard set in the original edition by Sir John Thomson-Walker has been well maintained by the present editor. Although adequate discussion of the various subjects in this field is included, emphasis has been laid on the surgical procedures involved in treating the various diseases. In spite of the fact that almost a thousand pages have been devoted to the various diseases of the genito-urinary tract, it was necessary to limit the discussion of many subjects to such an extent that in some instances it is inadequate. It is quite evident that our knowledge in this field is increasing so rapidly that separate monographs on the different subjects involved have become necessary in order to obtain thorough consideration.

In considering renal infection, the classification employed is somewhat elaborate and quite different from that adopted by most American urologists. It is of interest to note that the use of vaccines is still advocated. Although the important advances recently made in the treatment of infection in the urinary tract are referred to, they apparently were so recent at the time the book was published that they receive but scant consideration. This emphasizes the weakness of all textbooks in rapidly advancing fields such as urology in that the discussion of some subjects often becomes out of date before it is off the press.

In discussing the subject of renal tumor the classification is not in accord with recent views and could be greatly simplified. The term "hypernephroma" is retained and is regarded as distinct from adenocarcinoma, which in turn is differentiated from carcinoma. Tumors of the bladder are classified largely according to gross pathology. The cellular differentiation and classification of Broders, which is so widely accepted by American urologists, is not referred to.

The attitude of English urologists with regard to the treatment of renal mobility is interesting. English surgeons have always regarded this condition as amenable to surgery and, although it is recognized that some limitations should be made,

many of them seem to believe that nephropexy is indicated in most cases and that the urographic demonstration of stasis is not always necessary.

The discussion of transurethral (or "per-urethral" as the editor terms it) resection of the prostate gland is comparatively limited and quite inadequate. This is undoubtedly due to the fact that English urologists have been slow in adopting this method of removing prostatic obstruction. The editor states that in his opinion not more than 20 or 25 per cent of such cases will be amenable to per-urethral manipulation. This is quite in contrast to the experience and opinion of American urologists who have had broad experience in this field. Figures are quoted on the early failures and difficulties of a few American urologists, who with increased experience in the last few years have had results that are quite different.

Another illustration of the rapid march of urologic progress is shown by the absence of any mention of the treatment of gonorrhea and its complications by means of hyperpyrexia.

The chapters on diseases of the genitalia are quite complete, particularly in the description of surgical treatment. It is of interest to note, however, that no mention is made of the Aschheim-Zondek test in diagnosis of tumors of the testis. It may be said, however, that the book is an excellent treatise on the subject and deserves a place among the best of the rapidly increasing numbers of textbooks dealing with genito-urinary disease.

Sérothérapie antipoliomyélique d'origine animale (S. A. P.). (Selze années d'expérimentation clinique.) Par Auguste Pettit, professeur à l'Institut Pasteur. Paper. Price, 30 francs. Pp. 271, with 9 illustrations. Paris: Masson & Cie, 1936.

This is an account of the experiences in the laboratory and with the treatment of patients with acute anterior poliomyelitis by three types of animal serums produced by the author. A brief survey is given of the experimental background for the production of these serums. This is followed by a detailed account of the method of testing of the serums and their actual production in three hosts: a species of lower monkey, the chimpanzee and the horse. Concentration of these serums was practicable by a modification of Ramon's method for the concentration of pseudoglobulin, the antiviral activity being increased twentyfold. The last two thirds of the booklet is given to case reports, in the majority of which the serum (of one origin or another, mainly antiviral horse serum) was administered after the onset of paralysis. These reports taken individually or as a whole might well be compatible with the natural evolution of the disease. Indeed, the claims made for these serums in the conclusions, i. e., that paralysis is prevented when given in the preparalytic stage and that bulbar involvement and the spread of paralysis are halted when given after paralysis has set in, are not warranted on the basis of the evidence presented. In view of the capricious and treacherous course of this disease, in view of the larger number of preparalytic cases in which paralysis never occurs (about 80 per cent according to the American data) and in view of the unsettled state of even convalescent serum therapy in this disease, the use of an animal serum even though virucidal in vitro does not seem to be warranted.

Urology for Nurses. By Oswald Swinney Lowsley, M.D., F.A.C.S., Director of the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital, and Thomas Joseph Kirwin, M.D., F.A.C.S., Attending Urologist of the Department of Urology (Janet Buchanan Brady Foundation) of the New York Hospital. In collaboration with the entire nursing staff of the Department of Urology of the New York Hospital. Cloth. Price, \$3. Pp. 493, with 101 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1936.

This is an excellent volume for its purpose. Not only is there a good historical review and general consideration of the subject, but also it is written in a manner that is easily understood. The chapters on the care of urologic instruments are especially to be recommended. Discussion of the relation of nurse to patient, especially as concerns venereal disease, is not forgotten. Adequate description of the various technical and laboratory procedures is included, so that the student can gain an understanding into their application. With the exception previously noted, the discussion of urology is quite complete and is satisfactory. Perhaps the poorest section of the book is that on urology in females. This is unfortunate as a great deal of the urologic treatment of females is performed

by nurses. It is probable that, even though the fly leaf states that reference to other books is unnecessary, for this work another urology had best be consulted. A complete glossary is appended, the only weakness being in the manner of synonyms. For example, Hunner's ulcer is the only term given for a condition known by a variety of terms with which the average nurse might not be familiar. The index seems satisfactory. In general it seems that this volume lives up to its glowing advertisement and is well worth the price asked. It would be extremely valuable for the nursing profession and would not even be out of place in the urologist's library.

The British Encyclopedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. Volume II: Apraxia to Carriers in Infective Disease. Cloth. Price, \$12. Pp. 830, with 126 illustrations. London and Toronto: Butterworth & Co. (Publishers), Ltd., 1936.

This alphabetical consideration of medical practice proceeds from "apraxia" to carriers in infective disease. Among articles especially likely to attract wide attention are those dealing with arthritis, athletic injuries, birth palsies, blood examination, brain abscess, breast diseases, cancer, and carriers in infective disease. Volume II is just as handsome as the first volume from a typographic point of view. The material is printed on a fine paper stock, arranged on the pages for easy reference, beautifully illustrated with many colored plates, and written by authors who have achieved repute in the fields with which they are concerned. As in the first volume, the distinctly British character of the work is reflected by the use of the British Pharmacopeia and a failure to recognize many recent American medical contributions. There is a separate index to volume II, and an exhaustive index of the complete system will be made available when the series is completed.

Stammering. By Elsie Fogerty, Principal of the Central School of Speech Training and Dramatic Art. Cloth. Price, \$1.25. Pp. 64, with one illustration. New York: Greenberg, 1936.

This little handbook is divided into four chapters, dealing with the development of stammering in the child, curative work for young children, curative work at school age, and self cure at a later age. The author says that "stammering is a nervous trouble," and she attempts to give it an adlerian explanation, which may have some basis in fact but is entirely inadequate. The reference to fear is, on the whole, well handled, but the excellent work done by Ferenczi on the relation of tic to speech, and Coriot's studies in stammering are ignored. The last two chapters, outlining methods of treatment, appear to be good from the standpoint of breathing and vocal exercises, but again, as in the theoretical section, the author's opening sentence, "Stammering is a nervous trouble," is almost forgotten and this aspect is unfortunately handled.

Die anatomischen Namen: Ihre Ableitung und Aussprache. Von Professor Dr. Hermann Triepel. Anhang: Eigennamen, die Früher in der Anatomie verwendet wurden. Neu bearbeitet und entsprechend den neuen anatomischen Namen ergänzt durch Dr. med. et phil. H. Stieve, o. ö. Professor der Anatomie in Berlin. Eighteenth edition. Paper. Price, 3.90 marks. Pp. 89. Munich: J. F. Bergmann, 1936.

This is a guide to anatomic nomenclature and has had considerable success in previous years. Of special interest is the appendix, which contains names of investigators whose own names were previously associated with anatomic structures. It is, of course, customary in modern science to discard these eponyms.

Light: The Raw Material of Vision. By Thomas Hall Shastid, A.M., M.D., LL.B. Cloth. Price, \$2. Pp. 64. Ann Arbor, Michigan: George Wahr, 1936.

This booklet is merely a sketch introductory to a much larger work on a similar subject which the author, an eye physician, expects to publish soon. He presents his thoughts and investigations and a few new definitions on what he is pleased to call "the raw material of vision," carrying his ideas on light through the nature and source, the vision factory, and the way it operates. In language almost simple enough for the public, he discusses the nature of light and its behavior. Interspersed are philosophic musings and at times quotations from various poets.

The Lung. By William Snow Miller. Cloth. Price, \$7.50. Pp. 209, with 152 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1937.

In this book the author has collected more than 150 illustrations of the lungs, using most of the periodicals and textbooks available and including, as well, many from his own collection. The book is based on almost fifty years of study of the lung structure. The author uses the term "hilum" instead of "hilus." The book is magnificently produced; many of the illustrations are in colors. It includes a historical sketch, involving biographic notes of all the great investigators who specialized in a study of the lung. This is an invaluable reference work for all those who are concerned with knowledge of the lungs in any of its aspects.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Services: "Immediate Surgical Relief" Construed.—If an indemnity insurance policy contains a clause authorizing the insured to provide at the time of an accident, at the cost of the insurer, "such immediate surgical relief as is imperative," no hard and fast rule, said the Supreme Court of South Carolina, can be laid down by which to determine the extent of the surgical relief that is authorized. The nature of the injury and its severity must necessarily govern. The court thought that a proper construction of the clause was well expressed in *United States Casualty Company v. Johnston Drilling Company*, 161 Ark. 158, 255 S. W. 890, 34 A. L. R. 727, as follows: "Now, the words 'such immediate surgical relief as is imperative' as used in the contract of insurance obviously contemplates emergency or 'first-hand' relief, in other words, such relief as must be given instantly or immediately following the accident to prevent impending death or to assuage or prevent suffering. These words have no reference to such surgical and medical treatment and hospital charges and compensation for nurses and such other expenses as are incident to, and necessarily incurred in, the usual and ordinary treatment of the victim of the accident some time after the accident occurred and which are continued in order to restore him, if possible, to his normal condition, and by so doing to lessen the damages for which the person causing the injury would be liable."—*Dime Taxi Co. v. Central Mut. Ins. Co. of Chicago* (S. C.), 186 S. E. 391.

Optometry Practice Acts: Annual Registration Fee Used for Optometrical Research.—The petitioner was licensed to practice optometry in California. The legislature imposed an annual registration fee of \$12 on optometrists and provided that of this sum \$8 was to be paid to the University of California by the director of professional and vocational standards to be used solely for the advancement of optometrical research. The balance of the renewal fee, namely, \$4, was required to be paid into the state treasury by the director. When the annual renewal license fee for 1936 became due, the petitioner paid to the director of the department named the sum of \$4 and demanded that he be issued a renewal certificate for 1936. The director refused to do so and the petitioner applied to the district court of appeal, third district, California, for a writ of mandamus.

The petitioner contended that the exaction of \$8 for the support of the department of optometry of the University of California constituted an exercise of the taxing power rather than of the police power and that the exaction was unconstitutional because it denied to him due process and equal protection of the law and created an arbitrary discrimination between persons and classes of persons similarly situated. But, said the district court of appeal, the petitioner erred in referring to the science of optometry as the "business" of optometry, in contending that the license fee of \$12 was imposed as a tax for revenue purposes, and that such license fee, being imposed on a business, was limited to the amount necessary

for licensing, including reasonable compensation for supervision over the particular industry. The practice of optometry is more than a business, continued the court. It is a profession relating to the public health and, as such, is peculiarly subject to state control. That control is not exercised for the benefit of the licensee but for the protection of the state, and the legislature in the exercise of its police power may impose such proper restrictions as it deems necessary for the protection of the public. The right to practice a learned profession comes from the state and is subject to conditions imposed by the state and may be taken away for noncompliance with such conditions. One of the conditions imposed by the state on the right of a person to continue the practice of optometry in California is that he pay \$12 annually for the right so to do. He may either accept or reject the state's offer. If he rejects the offer, he may not be permitted to continue the practice. The disposition of the proceeds from the license fees collected from optometrists is a concern of the legislature and not of the members of the optometrical profession. The legislature, being vested with authority to determine the methods whereby optometry may be best regulated and the public interest protected, has concluded that such public interest may be best served by the maintenance and support of a department of optometry at the University of California, a branch of the state itself. This action is not subject to review by the courts. The petitioner's application for a writ of mandamus was therefore denied.—*Penington v. Bonelli (Calif.)*, 59 P. (2d) 448.

Dental Practice Acts: Revocation of License for Aiding Corporate Practice.—The California board of dental examiners revoked the license of the respondent, E. G. Masters, on the basis of a complaint charging (1) that he aided and abetted an unlicensed person to practice dentistry and (2) that he employed cappers and steersers to obtain business. The superior court, San Diego County, annulled the revocation order and the board appealed to the district court of appeal, fourth district, California.

The complaint, as a matter of pleading, was sufficient, said the appellate court. It alleged that the Western Health and Hospital Corporation, Ltd., was practicing dentistry by offering to perform, through its agents, operations or treatment of diseases or lesions of the human teeth, alveolar process and gums, for a fee; that the corporation engaged the respondent to perform such treatments and operations and that he therefore aided and abetted the corporation to practice dentistry. On proof of these facts, the court said, the board of dental examiners had jurisdiction to suspend and revoke the respondent's license. The dental practice act provides that a license may be revoked for aiding or abetting any unlicensed person to practice dentistry. A corporation cannot lawfully practice dentistry, nor may a corporation obtain a license to practice. If it does practice dentistry it is necessarily unlicensed practice. The word "person" includes a corporation as well as a natural person, and hence the term "unlicensed person" as used in the dental practice act includes a corporation which practices dentistry. It follows, said the court, that this accusation in the complaint against the respondent stated facts sufficient to constitute unprofessional conduct and grounds for suspending or revoking the respondent's license. The superior court, therefore, erred in annulling the judgment of the board based on this accusation.

The respondent was further charged with employing cappers or steersers to obtain business but, the court said, there was no evidence to sustain this charge. The record did not disclose that the respondent ever employed the Western Health and Hospital Corporation, Ltd., to obtain business for him. Two witnesses testified that a person at the office of the Western Health and Hospital Corporation, Ltd., gave them the name of the respondent as a dentist for the corporation along with the names of other dentists. This evidence was inadmissible as hearsay, said the court, and hearsay alone is not legally sufficient to support the accusation. The judgment of the superior court, therefore, that the evidence produced before the board of dental examiners was insufficient as a matter of law to prove this accusation was consequently affirmed.—*Masters v. Board of Dental Examiners of California (Calif.)*, 59 P. (2d) 827.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

- Chemical Compounds as Carcinogenic Agents. J. W. Cook, G. A. D. Haslewood, C. L. Hewett, I. Hieger, E. L. Kennaway and W. V. Mayneord, London, England.—p. 219.
Carcinogenic Activity of Cholanthenes and of Other 1:2-Benzanthracene Derivatives. L. F. Fieser, Mary Fieser, E. B. Hershsberg, M. S. Newman, A. M. Seligman and M. J. Shear, Boston.—p. 260.
Studies in Carcinogenesis: IV. Development of Liver Tumors in Pure Strain Mice Following Injection of 2-Amino-5-Azotoluene. M. J. Shear, Boston.—p. 269.
Pure Strain of Malignant Mesenchymal Cells, Originating from Rat Sarcoma Produced by 1:2-Benzpyrene. L. Doljanski and L. Halberstaedter, Jerusalem, Palestine.—p. 285.
Medullary Carcinoma of Suprarenal Gland (Pheochromocytoma). M. J. Fein and F. F. Carman, Montclair, N. J.—p. 301.
*Iso-Agglutinins in Association with Malignant Growth. Anna Goldfeder and J. L. Fershing, New York.—p. 307.
Transplantation of Tumor Cells to Normal and Preirradiated Heterologous Organisms. J. Clemmesen, Aarhus, Denmark.—p. 313.
Chemistry of Cell Division: VI. Inhibition of Tumor and Liver Nuclease by Arsenicals. Mary E. Maver and C. Voegtlin, Washington, D. C.—p. 333.
Spectrographic Studies of Cancer and Normal Blood Plasma: III. Ultraviolet Absorption Spectrums of Fractionated Immune and Normal Rat Blood Plasma. Rachel G. Franklin, L. Smith and A. J. Allen, Philadelphia.—p. 341.
Experimental Serum Studies: Part II. Effect of Experimental Serum on Cell Respiration in Vitro of Sarcoma 180. Anna Goldfeder, New York.—p. 344.
Lack of Estrin Concentration in Adenofibroma of Mammary Gland in Rats. F. E. Mohs, Madison, Wis.—p. 356.
Influence of Wheat Germ Oil in Diet on Induction of Tumors in Mice. A. Haddow, London, England, and Helen Russell, Edinburgh, Scotland.—p. 363.

Iso-Agglutinins in Association with Malignant Growth.

—In view of the diversity of opinion, Goldfeder and Fershing made a study of 300 cancer cases in which the diagnosis was confirmed by histologic study after biopsy or necropsy. It differs from reports of previous investigators in that the percentage distribution of blood groups was studied not only in relation to the number of unclassified malignant manifestations but also in relation to anatomic location and to histologic type. All blood groups were represented among the 300 cancer cases. An analysis of the observations shows a marked difference in the distribution among the blood groups, of cancer of different sites. For instance, among the forty-four patients with malignant conditions of the breast, 43 per cent belong to group O, while among forty-one with malignant diseases of the cervix, only 26 per cent belong to group O. Among fifteen patients with cancer of the larynx, 46.7 per cent belong to group O, while none belong to group AB. Among eighteen cases of malignant disease of the mouth, 44 per cent fall in group O, 44 per cent in group A, 6 per cent in group B and 6 per cent in group AB. Of seventeen malignant disorders of the face, 47 per cent belong to group O, 35 per cent to group A, 18 per cent to group B and none to group AB. Among twenty malignant changes of the stomach, 55 per cent belong to group O, 25 per cent to group A, 20 per cent to group B, and none to group AB.

Significance of Icterus Index in Proctologic Disorders. J. Gerendasy, Elizabeth, N. J., and R. V. Gorsch, New York.—p. 940.
- Aluminum Preparations and Secretory and Gastric Acidity of Normal Stomach.**—Ivy and his associates determined the normal gastric response of six graduate students, accustomed to the stomach tube, to 50 cc. of 7 per cent alcohol, after evacuating the gastric residuum. The alcohol test was performed with aluminum preparations immediately after taking the alcohol. The curves of the average response of the group for two hours shows that the aluminum preparation reduced the free acidity for forty-five minutes or longer. The variation in the response from subject to subject was rather marked, and the tendency to an increase in acidity after the aluminum had been evacuated was characteristic of four of the six subjects.

Tolerance of Cardiac Patients for Certain Recumbent Positions.—Wood and Wolferth use the term trepopnea for the phenomenon observed in certain cardiac patients who can lie comfortably in one recumbent position, usually the right

lateral, but cannot tolerate another recumbent position, usually the left lateral, and are forced to abandon the latter for the former by symptoms that they cannot endure. This phenomenon is just as common and just as definite as orthopnea. There are certain indications that trepopnea and orthopnea are related and that they may be manifestations of the same type of underlying mechanism. Patients group themselves into four general categories: (1) those who can lie comfortably in any recumbent position, (2) those who prefer one position or object to another for relatively minor reasons, (3) those who experience dyspnea and discomfort in the chest when in the unfavorable position but who can endure it and (4) those who are actually forced to abandon one recumbent position for another by symptoms that they cannot endure. The last two groups constitute the material on which the authors' discussion is based. The symptoms that forced patients to change from one horizontal position to another were usually dyspnea and discomfort in the region of the heart. Less common manifestations that compelled them to move were coughing and anginal pain. Most of these patients showed considerable cardiac enlargement and a marked reduction of the functional capacity of the heart. No regularly occurring cardiovascular characteristics have been observed by which these patients with position preference can be differentiated from those with orthopnea, but in most engorgement of the veins and liver was more prominent than engorgement of the lungs. When a patient moved from a favorable to an unfavorable position there was usually a latent period before the appearance of symptoms. This period varied from ten seconds to two minutes (average about twenty seconds). The respiratory phenomena were variable. Certain patients showed a rapid rise of their respiratory rate to double the original and an apparent lessening in depth. Others showed a change of facial expression from one of relaxation and comfort to one of anxiety and apprehension and complained bitterly of dyspnea but did not increase their respiratory rate, and their breathing was not deepened. If these observations are supported by careful measurement of minute volume, they indicate that the dyspnea which is the principal complaint of these patients is a subjective sensation, which may or may not be accompanied by obvious change in the rate or depth of breathing. On fluoroscopic study, forty-nine subjects fell into three groups: fourteen with no demonstrable heart disease and no trepopnea, fifteen with heart disease without definite trepopnea, and twenty with heart disease and real trepopnea. In a few instances, systolic murmurs seemed to become louder after the patient had maintained the left lateral (unfavorable) position for a few minutes. The conclusion seems justified that this phenomenon cannot be accounted for by vital capacity changes or by variations in relative levels of the right auricle and the respiratory center. The authors believe that trepopnea is due to movement of the heart in the thorax as the patient changes position and that this movement causes pressure on certain mediastinal structures, which gives rise to the signs and symptoms. Patients in whom this phenomenon is marked do not assume their most unfavorable position at night, even when asleep. Those in whom it is less well developed are sometimes found in an unfavorable recumbent position during sleep, although they may assert that they cannot tolerate this position.

Action of Carbinoylcholine in Peripheral Vascular Disease.—Starr first administered carbinoylcholine chloride in increasing dosage to twenty-six normal young adult volunteers (from 0.1 to 1 mg. subcutaneously and from 0.4 to 1 mg. orally). With this experience behind him he employed it in the treatment of disease conditions which its action seemed adapted to benefit. The drug causes striking relief of pain in certain cases of peripheral vascular disease without any increase in skin temperature of the affected part. This raises the question whether the relief secured is due to something else than vasodilatation. In the author's opinion the skin temperature method of estimating peripheral blood flow is too crude to permit one to place much emphasis on a negative result. He attributes the relief of pain to vasodilatation of a grade too slight, or in vessels too deep, to be detected by this method. The information now at hand concerning its dosage, action and untoward effects is sufficient to warrant its cautious use in cases in which its action seems adapted to be beneficial.

Ocular Lesions Associated with Nutritional Deficiency.

—Wagoner and Weir point out that the occurrence of hemeralopia and xerophthalmia among persons whose diet is deficient in vitamin A has been well established. That deficiencies of other vitamins can cause lesions of the eye has not been so clearly demonstrated, although a number of clinical and a few experimental reports can be found in the literature. It seems probable that, in the average case, inadequate amounts of several rather than of single vitamins are concerned in the production of the deficiency syndrome. Deficiency of vitamins in the organism may be produced by inadequate amounts in the diets, by deficient absorption from the intestinal tract or by increased consumption during rapid growth or during a severe disease. In at least two of the postoperative cases presented by the authors, prolonged vomiting was apparently the basis for the nutritional deficiency. The administration of vitamins caused the absorption of hemorrhages in the retina in their second case of pernicious vomiting of pregnancy before the interruption of the pregnancy. The hemorrhages in Stander's case, present three weeks after the induced abortion, suggest the influence of nutritional deficiency in the causation of the retinal hemorrhages. It seems probable that acute optic neuritis, hemorrhages in the retina, paralyzes of ocular muscles and nystagmus may be caused by dietary or nutritional deficiencies. These deficiencies may develop rather rapidly, especially in the presence of persistent vomiting and the resultant lack of absorption of food.

Sakel's Treatment of Schizophrenia.—Sakel's treatment of schizophrenia consists essentially of the production of consecutive daily shocks with high doses of insulin; these occasion-

ally provoke epileptic seizures but more frequently produce somnolence or coma, accompanied by profuse perspiration—in any case a clinical picture that would ordinarily be alarming. The patient may show sudden improvement after the first shock, but more often there is a gradual improvement after a series of shocks. In this phase of treatment, however, the response is still fluctuating and unstable, so that further treatment is necessary to stabilize the remission. The method of treatment may be dangerous in unskilled hands. When it is considered that the patients who come for treatment are generally looked on as lost or very seriously ill in any case, there is good justification for attempting a therapy, however dangerous, which gives some promise of success. The experience that the author has had up to now is promising.

Weak Foot.—Success in the treatment of the common type of weak foot due to poor posture depends on the intelligent employment by the physician and the patient of five separate but simultaneous lines of attack: maintenance of correct posture, proper use of the foot in walking, exercises for the reeducation of the foot and leg muscles, properly constructed shoes that fit correctly, and a temporary crutch in the form of an arch support. Graham has in mind the uncomplicated weak foot. In the treatment of the complicated weak foot there is a basic attack directed always toward the primary distortion of physiology, maladaptation of the weight bearing mechanism to the superstructure, and a secondary attack varying in nature with the complication. No matter whether the clinical condition present in a given case is simple weak foot or complicated weak foot, the basic attack is the same, regardless of variations that must be made in the secondary attack. The common type of weak foot is that associated with poor body posture. The sequence of events appears to be slouch posture with a forward shift of the line of gravity of the body, lumbar lordosis, increased pelvic tilt, internal femoral rotation, internal astragalar rotation, and valgus relation. Absolute cooperation of the patient is essential, since the plan of treatment has as its goal the development in the individual of a consciousness of posture that is followed eventually by a posture reflex. This necessitates first of all the instruction of the patient in the elements of correct posture. The "wall and chair maneuvers" are described in this connection. Development of neglected muscles through exercises enables the patient to pull himself into correct posture and to stay there. This act in time becomes reflex. The foot cannot function efficiently when the shoe covering it is not properly constructed and correctly sized. Patients for postural correction must be selected with care, since readjustment of a posture that has been maintained for years is a serious matter.

Simple Mastectomy in Cancer of Breast.—An evaluation of the results of radical surgery, when studied comparatively with a corresponding group of cases with simple mastectomy and radiation, leaves Grace convinced that the rôle of surgical radicalism is far removed from surgical idealism. A series of forty simple mastectomies with irradiation, after a five year

follow up, is compared with other larger series of radical mastectomies. The latter groups represent a total of 1,276 radical mastectomies. There was a marked similarity in the end results, whether radical or simple mastectomy is done. The cellular structure of the tumor is the dominant factor, and surgical technic, irrespective of the extent of its radicalism, plays a definitely secondary part.

Therapeutics of Maggot Active Principle.—Livingston points out that 415 cases have been treated by living maggots and maggot active principle in combination, and 605 cases by maggot extract alone. Living maggots have been used only in large suppurative, copiously discharging wounds because of the mechanical difficulty of introducing a fluid into such a wound. When the exudate decreased, the maggot active principle was substituted for the living larvae and used either as a drip or as a wet pack. The wounds, when stimulated by maggot active principle following a débridement or a radical sequestrectomy, quickly filled with pink healthy granulation tissue; granulations sprang from the depths of the medullary cavity and from the walls of the wound, completely filling the cavities to the level of the skin. Epithelization completed the process without a depressed scar. The period of healing was from six to twenty weeks. The extract is stable at room temperature and was found to be still active when tested after six months on the shelf. The psychic trauma of living maggots is eliminated. It is a more powerful growth stimulant than any one of its ingredients, which were used alone as a control. The extract has a wider applicability than living maggots. Maggot extract was successful in only 5 per cent of the cases of tuberculous origin; there was failure to respond satisfactorily in 12 per cent of the cases of chronic pyogenic osteomyelitis having a large involucrum incorporating multiple foci of infection, cases of chronic pyogenic osteomyelitis undergoing molecular necrosis or cases having positive blood cultures.

Hyperpyrexia in Treatment of Blennorrhagic Keratoderma.—Epstein obtained a successful result in a case of blennorrhagic keratoderma by inducing hyperpyrexia artificially. The method employed to raise the temperature was a slight modification of that described by Norman Epstein and Cohen in 1935. An oral temperature higher than 106.5 F., a pulse rate more rapid than 160 beats per minute or a respiratory rate in excess of 40 per minute is considered to be at a dangerous level. When the oral temperature reaches 103.5 F., the heat cradle is removed and the rubber sheet and the large blanket are then wrapped directly around the patient. A hypodermic injection of one-third grain (0.02 Gm.) of the hydrochlorides of the alkaloids of opium, principally morphine, is given when the cradle is removed in order to control restlessness. Fluids are administered orally during the treatment, 200 cc. of warm lemonade (100 F.) being given after each recording of the pulse, temperature and respiratory rate. The lemonade is sweetened to taste and 0.6 per cent sodium chloride is added to aid in replacing the chlorides lost through perspiration. When the patient has spent four hours at a temperature in excess of 103.5 F., the blankets are removed and the patient is given an alcohol sponge bath. Treatments are usually repeated every other day. The oral administration of cod liver oil was the only other therapeutic agent employed in the treatment of the patient. Prompt relief from gonorrheal urethritis, arthritis and keratoderma were obtained.

Treatment of the Child with Adult Type of Active Pulmonary Tuberculosis.—Gross and English have treated forty-nine cases of the adult destructive type of disease in the juvenile by some form of compression therapy for a period of from six months to five years. Their ages have been from 5½ to 15 years. Whenever artificial pneumothorax could be given, the results were far superior to those of any other type of compression therapy. Twenty-four patients received unilateral collapse with two deaths. Both fatalities occurred in the first month, being far advanced, hopeless cases. Twelve patients received unilateral compression which required an additional phrenic crushing to help close the cavernous processes because of interfering adhesions. In this group there were four deaths, three of the patients dying after two years of unsuccessful collapse of the disease process and one patient one year after collapse was started. The last fatality had in addition an intrapleural pneumolysis followed by a putrid empyema. Five patients received bilateral artificial pneumothorax, with two fatalities. No free pleural space could be found in four patients and therefore phrenicophax was performed. In two cases the cavities are practically closed and in two others no improvement is noticeable. In four other cases, phrenic crushing was performed because it was deemed inadvisable to give artificial pneumothorax, owing to the far advanced, hopeless condition of the patients. Two are dead, one having died six months following entrance and the other eighteen months after admission in another institution. The third patient is in poor physical condition and has been at home for the last three and one-half years. The fourth patient has been in another institution for the last three years, ambulant but having active tuberculosis. In all the fatal cases there were persistent, positive sputum, marked pulmonary involvement and cavernous processes, making it impossible to get the disease under control from the very start. They were all progressive cases. The adult disease in juvenile cases is practically of the same type as that seen in adults with the exception of some peculiar, unexplained reason that the children do not seem to handle the disease as well. The procedure of choice is artificial pneumothorax. The authors' best results have been obtained in cases in which a free pleural space could be found and this procedure applied and adequate collapse obtained. The aim of those doing compression therapy, especially artificial pneumothorax, should be an optimal compression, conducive to successful collapse of the diseased lung. One should not hesitate to do bilateral artificial pneumothorax if indicated. These patients are generally in need of such procedures, and the outlook without compression is doubtful. Children having positive sputum should be separated from those having negative sputum, as cross infection can and does occur.

Tuberculosis and Malignant Tumors.—Moore and Schmeisser studied the incidence and relation of tuberculosis and malignant tumors in the same individual as seen from the protocols of 2,000 consecutive necropsies. Without regard to race, sex or age the 2,000 cases were divisible into three general incidence groups: 131 cases of malignant tumor, 480 of tuberculosis and 1,410 cases showing no evidence of tuberculosis or a malignant tumor. Therefore it will be seen that the total

number of cases in which both tuberculosis and a malignant tumor existed numbered only twenty-one. If a comparison is made between this double-lesion group and the total number of cases in each of the two disease groups, it is found that 4.37 per cent of all people with tuberculosis also have a malignant tumor, while 16.03 per cent of all people with a malignant tumor also have tuberculosis. Therefore, while the incidence of the double-lesion group as compared to the total number of necropsies is relatively low, the incidence assumes greater importance when compared with the two disease groups in question.

Sterility Following Injection Treatment of Hernia.—To study the possible sterility in cases of bilateral inguinal hernia treated by the injection method, Rea performed ejaculation tests. If this was unsuccessful, prostatic smears were examined for spermatozoa. In fifteen cases in which ejaculation tests were performed after treatment, all were normal. Ejaculation tests were obtained before and after treatment in two cases; one of the patients had had an operative repair on one side. In eight patients from whom prostatic smears were obtained, no spermatozoa were found. Three of these patients had a chronic prostatitis. Two patients, both of whom showed abnormal mental traits, complained of less libido three months and five years, respectively, after hernial injections. Of seventy-five cases of unilateral inguinal hernia, followed up to two years, only one patient complained of less libido after a course of sclerosing injections. As to impotence following injections, the type of patient is probably the most important factor. Sterility therefore does not appear to be a complication of the injection treatment of hernia. Fear of such an occurrence should not deter employment of this method in selected cases of inguinal hernia.

Partial Pancreatectomy in Convulsive States Associated with Hypoglycemia.—McCaughan and Broun advise that desperate cases of convulsive seizures associated with

hypoglycemia unrelieved by proper dietary and medical treatment be offered the opportunity afforded by surgical exploration. Adenomas if present may be removed, with excellent prospects for cure. If no tumors are found, the pancreas can be partially extirpated without undue risk. The amount to be removed will depend on the severity of the symptoms and the anatomic and pathologic conditions at hand. If the pathologic changes in the resected portion show islet hypertrophy or small adenomas, a case improved by resection can be offered the benefit of additional resection if conditions are favorable for further operative procedure. From a study of case reports in the literature it is evident that the end results of operations in cases with islet cell tumors are excellent, and in cases without adenomas the results, while much less satisfactory, are occasionally gratifying. The authors' results in their series were very disappointing and should dampen the enthusiasm of those who may be inclined to recommend surgery for the relief of any and all cases of hypoglycemia with nervous manifestations. Until a positive method for differentiating cases of pancreatic adenomas from other functional abnormalities of the islet cells, particularly those due to an imbalance between inter-related endocrines, is developed subtotal resections of the pancreas will continue to be unfavorable. The comparison of subtotal pancreatectomy for hyperinsulinism with the rationale of thyroidectomy for hyperthyroidism, as has been suggested by some, seems scarcely tenable in view of the uncertain and the generally unsatisfactory clinical results thus far reported in cases without adenomas of islet cell origin.

Preoperative Irradiation in Tumor of Testis.—Randall and Bothe feel that irradiation should precede surgery in tumors of the testicles but that it should never supplant it entirely. Irradiation of testicular tumors has a definite destructive effect on the immature embryonal cells but little or no effect on the differentiated types. These observations are in keeping with the laws governing cellular radiosensitivity. Regardless of the degree of clinical improvement, irradiation does not entirely destroy the neoplasm. In that class in which there are occasional viable cells remaining which appear to have the power of regeneration, it is felt that these tumors should be removed surgically, after the maximal regression from irradiation has been obtained. Procrastination after effective irradiation leads to disaster. The most favorable time for removal is usually between the fifth and the sixth week. Orchidectomy alone has given less than 10 per cent of cures; radical surgery by orchidectomy, with the removal of the entire lymph drainage area, has raised this figure to 19 per cent, and irradiation alone has produced 29 per cent of cures. Irradiation alone cannot be relied on to produce a cure because of resistant cells; nor can a cure be appreciated, measured or established by any clinical test. Therefore, orchidectomy is mandatory as a secondary procedure. Irradiation should be widespread in its application and should include the entire body above the primary lesion.

Renal Insufficiency from Blood Transfusion.—The interest of DeGowin and his associates in renal insufficiency following transfusion was stimulated by the occurrence in the University Hospital of two fatal cases of renal insufficiency

following blood transfusion. As clinical experience and a review of the literature pointed to no promising therapeutic procedures in this condition, they attacked the problem experimentally. So far they have made studies on a series of twenty-eight dogs over a period of more than two years. More than 100 transfusions of dog hemoglobin have been given. It was found that when the urine is alkaline the intravenous injection of a large amount of dog hemoglobin into dogs seems to be innocuous. Under such conditions four dogs received a total of thirty-eight transfusions without harm. In one of the dogs, retention of nitrogen developed on three occasions when the transfusion was given while the urine was acid. When the urine is acid, transfusions of hemoglobin sooner or later produce renal insufficiency. Seven dogs died in coma from four to ten days after the transfusion, with the urea nitrogen values of the blood ranging between 120 and 362.6 mg. per hundred cubic centimeters and creatinine values between 4.6 and 15 mg. One dog was killed when recovering, the urea nitrogen content of the blood being 95 mg. Only one dog survived seven transfusions when on an acid diet. This syndrome, clinically and chemically, closely simulates that which develops in human beings with renal insufficiency resulting from hemoglobinuria. The cause of renal insufficiency resulting from hemoglobinuria in dogs appears to be the obstruction of the tubular lumens with masses of pigment derived from hemoglobin. These studies substantially confirm the experiments performed on rabbits by Baker and Dodds.

Osteomyelitis and Suppurative Joints.—Brockway does not believe that restoration of motion in a pus-ridden joint is aided by a long period of immobilization. It is in support of this contention that he describes the salt water pool treatment of bone and joint infections. While he has used this treatment in more than 100 cases of osteomyelitis, his discussion is concerned only with thirty cases of suppurative arthritis and osteomyelitis in which adjacent joints are also involved or when the disease process closely encroaches on joint structures. It is in these particular types of cases, in which preservation of joint motion is one of the vital issues, that the treatment has its greatest field of usefulness. Motion of an infected joint should not create muscle spasm. It should be painless and free of the fear of pain, and there should be no discomfort in the joint after the patient returns to bed. The use of the salt pool satisfies all these requirements. Motion in the water mechanically cleans away the infection, and because the water is hypertonic there exists an osmotic pressure between this fluid and the body fluids, so that drainage is encouraged and accelerated from the innermost depths of the wound. The salt concentration of the water in the pool is between 6 and 7 per cent. At this concentration the water sterilizes itself, as cultures have always been negative. The temperature of the pool is maintained at about 96 F. and the treatment lasts about thirty minutes. The floor of the pool should be sloping, so that weight bearing on an infected joint can be gradually increased. The weight of the body standing in water is the weight of that part of the body above the water line. For the eight cases of suppurative arthritis without bone involvement the average time required for healing was 2.8 months, and complete motion was restored in every case in an average of five months. It has been the author's practice in cases of osteomyelitis involving the ends of long bones and in which there is an accompanying suppurative arthritis to do a wide saucerization of the bone, removing as much of the diseased bone as possible and packing the wound lightly with petrolatum gauze, as in the Orr treatment. The joint is also opened and irrigated. A plaster cast or spica is applied, depending on the bone involved. The cast is removed in from four to six weeks, which is about the time the first

change of cast is made in the Orr treatment. A splint is applied and daily pool treatment started. In the twelve cases of this type return of motion was complete in four and one-half, normal in five, and ankylosis occurred in four. There were ten cases in which the osteomyelitic process, while not involving the joint proper, was in very close approximation to the joint, involving at times the epiphyseal plate. In these ten cases the disease process was in close approximation to thirteen joints. There was complete return of motion in seven, and in the other six the residual motion averaged about one-half normal.

Dissecting Aneurysm of Aorta.—Agnor groups clinical phenomena taking place in dissecting aneurysm of the aorta under four primary clinical features. 1. The mode of onset is characteristically abrupt. It follows at once, or within a few hours, many forms of physical stress. 2. Pain is the outstanding symptom. It is described as violent, sharp, knifelike, tearing or rendering, and is extreme in its intensity. It is usually precordial, but its segmental distribution is likely to be higher than the pain of coronary disease. Its radiation may be down the outer rather than the inner side of the arm. It is constant and continuous, and morphine alone will give relief. With the progress of the dissection there is pain in the back, in the abdomen, in the lumbar or sacral region and even running down the leg. 3. Among the abnormal circulatory phenomena there are various harsh, rumbling or hissing systolic murmurs heard over the heart and great vessels. The pulses are frequently unequal or absent in various regions. Bilateral blood pressure readings are helpful. Often one limb or part of a limb may become cool and pallid, and even gangrene may develop. 4. The effects of disturbances of circulation in other organs or systems are many. There may be complete obstruction of the carotid circulation with encephalomalacia, hemiplegia and death. The coronary circulation is less frequently interrupted. There may be sufficient compression of the renal arteries to produce anuria. Cases in which there was paralysis as a result of interference with the blood supply of the spinal cord have been encountered. There may be pain between the shoulder blades at the onset. The pain may be largely epigastric, and an acute peritoneal irritation may be suggested.

Recurring Inguinal Hernia. C. L. Wilmoth, Denver.—p. 101.

Potential Malignancy of Small Skin Lesions.—Sutton asserts that malignancy is not potential; it is there from the start or not there at all. "Cancer" does not connote a lesion that will eat one's head off in three weeks; it connotes a colony of cells derived from an altered mutant somatic cell, which may grow swiftly or slowly or not at all. The "warts" are not warts; they are cancer from the start. They do not degenerate, they grow. They do not become malignant; their cells are malignant. Malignancy resides in the cellular units of the lesion. Given the presence of a malignant condition, it is measured by their proliferative rate as compared with the proliferative rate of normal cells. The mutation theory of the origin of cancer is eminently satisfactory philosophically, biologically and practically. No better explanation of the cause of cancer will be evolved until the chemistry and physiology of chromosomes and their component genes is better understood. The cure of cancer lies in its early recognition and adequate treatment, preferably with the hot iron. Wide excision is the safest and most secure therapeutic measure, excepting lesions superficial enough to be blistered off without necessitating excision.

Observations on Use of Protamine Insulin. H. S. Everett, St. Stephen, N. B.—p. 58.

Complications of Diabetes Mellitus.—Piper discusses coma, neuritis, infection, gangrene, arteriosclerosis and associated heart degeneration as the complications of diabetes mellitus. Diabetic coma must always be considered an emergency and treated as such. Before the use of insulin it was almost 100 per cent fatal and since the use of insulin it is almost 100 per cent curable if handled properly. The diagnosis of diabetic coma is established by always finding the blood sugar elevated to a high degree and the combining power of carbon dioxide decreased markedly. Neuritis is a troublesome complication of diabetes. There is no special treatment for this condition, except to control the diabetes in the best possible manner. The neuritis may persist for a long time after the diabetes is under control, but recovery almost always occurs. There is little evidence to show that diabetes is caused by infection but a great deal of evidence that it is made worse by it; in fact, mild diabetes may be turned into a very severe form of this disease. Infections are very prone to occur in the diabetic patient and advance rapidly. Hence a vicious circle

is set up. The diabetes is made worse by the infection and the infection is aided by the diabetes. In treating these infections this vicious circle must be broken and the best way is to incise freely all pus pockets and institute free drainage. The best known treatment for infection in the known diabetic patient is prophylaxis, by teaching the patient the proper hygiene of all parts of the body. The several types of gangrene in diabetes are the arteriosclerotic, obliterative endarteritic, embolic and obliterating thrombo-angiitic and diabetic. The diabetic form is distinctive from the others in that the gangrene spreads laterally as well as along the vessels or line of circulation. Circulation is always interfered with in these cases. Then if a very slight infection takes place, which may come from as small an injury as a cut on the toe from trimming the toenail, gangrene is apt to set in. Sometimes the infection seems to come from within. Conservative treatment can be carried out only on the diabetic gangrene, and this is probably successful only in the early cases. Conservative treatment does not offer much in the first three types of gangrene. The mortality of amputation cases is fairly high. Most of these patients die from septicemia and bronchopneumonia. Joslin states that the average span of life after amputation is two years. He believes that arteriosclerosis is secondary to diabetes and that the duration of the disease is an important factor in the production of it. He found that diabetes of a duration of five years or longer is practically always complicated by arteriosclerosis. It has been shown that arteriosclerosis progresses in the diabetic patient in spite of the proper treatment with diet and insulin. Every diabetic patient should receive a searching examination, especially relating to the condition of the heart muscle and for coronary damage. Distinct damage may be done by the use of insulin in the treatment of these cases, and death may ensue in some of them.

Mammography.—Hicken believes that contrast mammograms and aeromammograms have a definite diagnostic value. He presents seven cases. Injection of the estuaries is occasionally a tedious procedure and in some instances cannot be accomplished. No injection or manipulation should be done in the presence of an acute infection. As soon as the mammographic studies have been completed a gentle milking massage of the nipple expresses the major portion of the injected

medium, thus minimizing the amount to be retained. Application of the breast pump has likewise proved effective in decompressing the injected lobules. In nearly every instance in which a lactating breast was injected the patient experienced some soreness and discomfort for a period of from twelve to twenty-four hours. In thirty-five instances there was no interference with the flow of milk, and no mastitis or infection occurred. The transitory pains were of a mild nature and easily controlled by the application of hot moist packs. Strict surgical asepsis should be practiced lest an infection be introduced. Diagnostically, the contrast mammograms are far superior to the soft tissue roentgenograms in the recognition of mammary tumors. In each of the seven cases presented the mammographic studies gave an excellent visual pattern of the offending neoplasms, while the soft tissue roentgenograms were either indefinite or completely void of information. Papillomas, simple retention cysts, cystic degeneration of the breast, galactoceles, carcinomas and retention mastitis were diagnosed by mammographic studies. Of the 314 mammograms made but one breast abscess resulted, and in this instance the patient had a pyogenic mastitis prior to injection studies.

Resistance of Sphincter of Oddi in Man.—Doubilet and Colp made measurements of the resistance of the sphincter of Oddi obtained in patients who have had a T tube intubation of the common bile duct. A method was developed for the kymographic recording at the bedside of the resistance of the sphincter to the flow of fluid in the duodenum. Advantage was taken in these cases to observe the effect of local application of drugs to the periampullary region of the duodenum and of hypodermic injections of the various drugs commonly used in clinical practice. Spasm of the common duct sphincter has been shown to exist in human cases. Ingestion of food does not cause sphincteric relaxation in the absence of the gallbladder. Duodenal lavage with magnesium sulfate causes relaxation of the sphincter. Instillation of diluted hydrochloric acid into the duodenum causes temporary sphincteric spasm. This reflex is prevented by atropinization. Morphine produces severe sphincteric spasm, which lasts more than three hours. This spasm is not influenced by atropine. Papaverine may produce a temporary relaxation of a spastic sphincter but ordinarily has slight effect. The effect of epinephrine on the sphincteric resistance was negligible.

Pelvic Variations in Primiparous Women.—Thoms emphasizes the advantages of applying the newer knowledge of pelvic variations to practical obstetrics and presents a survey of the results in 300 primiparous white women who have been delivered consecutively at full term in whom roentgenometry of the pelvis has formed a part of the antepartum examination. He has used roentgenometric methods almost as a routine for nearly four years, and he is convinced that their use has simplified many obstetric problems. For example, in none of the cases presented was "the test of labor" used and, from the fact that cesarean section was performed only six times in 300 consecutive primiparous women, it appears that radical measures were not substituted for the more conservative procedures. Exact dimensions of the pelvis as revealed by roentgenometry are not a substitute for careful obstetric judgment as developed by clinical experience. The information thus obtained, like paint on an artist's easel, must be "mixed with brains." The employment of the contour of the superior strait as a basis for classification will allow all but the most abnormal pelves to be readily grouped. If other features of obstetric importance present themselves, such as the male type of sacrosciatic notch, narrow forepart, narrow subpubic angle, and forward displacement of the lower sacrum, these features may be noted. Every woman who is expecting her first baby deserves the advantages offered by roentgenometry of the pelvis.

Experiments in Prophylaxis of Influenza.—Andrewes and Smith carried out experiments on mice with a view to obtaining the most favorable antigen for trial as a prophylactic for influenza in man. Their objectives were to obtain a suspension with as high a virus content as possible, to purify this by freeing it from undesirable constituents and to inactivate the virus, if possible, without destroying its antigenic value. Subcutaneous and intraperitoneal inoculation of living influenza virus into mice confers on them substantial immunity against intranasal infection. Influenza virus can be purified partially by washing on a collodion membrane without great loss of titer; this washed virus immunizes mice as effectively as does crude virus. Influenza virus inactivated by 1:5,000 or 1:10,000 formaldehyde immunizes mice almost or quite as effectively as does living virus. Virus inactivated by formaldehyde as strong as 1:1,000 still makes a good vaccine and keeps its potency, at least in part, for two months in the cold. Influenza virus that has been both purified by washing and inactivated by formaldehyde makes a relatively poor vaccine for mice. Preliminary experiments on five human beings indicate that subcutaneous inoculation of influenza virus inactivated with formaldehyde will produce in at least some subjects a substantial rise in their neutralizing antibodies for influenza virus. The W. S. strain (unfiltered suspensions) of influenza virus appears in the course of passages through mice to have undergone a rather sudden spontaneous change of such a nature that it is now possible to obtain filtrates of from ten to 100 times as high a titer as formerly.

Healing of Cavities in Pulmonary Tuberculosis.—Hudson asserts that the most desirable way of causing the obliteration and healing of a cavity is by rest, climatic treatment and time. This natural healing certainly may occur and is without any doubt favored by residence in the Alpine climate. Usually, if closure is going to take place in this climate, it shows signs of doing so fairly rapidly—in from three to six or seven months.

If after that time no sign of change, alteration in shape or diminution of the size of the cavity can be seen, it is very unlikely that it will close by natural means. Owing to the altitude of the Alps, the air is rarefied and the barometric pressure lower than at sea level; therefore the partial pressure of oxygen is correspondingly diminished. The physiologic effect of this is that breathing becomes deeper in order that the tissues may receive their proper oxygenation. For the same reason the blood changes its character, the red cells and hemoglobin showing an increase. The total amount of the blood is also actually augmented. The air, being drier, has a stimulating effect on the respiratory membranes. There is also a remarkable absence of wind and dust, especially during the winter months when the snow is on the ground. The Alpine climate exerts considerable influence on the metabolism and general health of a patient, and locally on the respiratory mechanism and membranes.

Influence of Vitamin C on Sensitivity to Tuberculin.—Heise and his co-workers determined the influence of vitamin C on the blood sedimentation rate and the tuberculin skin test in thirty tuberculous patients; six were used as controls. The urinary excretion of vitamin C was previously determined in each from a twenty-four hour specimen of urine. The sedimentation rates were determined immediately before the use of vitamin C and again after the final injection. Preliminary subnormal urinary excretion of vitamin C was demonstrated in nineteen of those receiving added vitamin C and in all the controls. Of the nineteen with preliminary subnormal urinary excretion of vitamin C, 47 per cent showed a significant decrease and 10 per cent an increase in sedimentation rate following vitamin C injection; 43 per cent showed no change. Of five patients with previously normal vitamin C urinary excretion, none showed significant changes in the sedimentation rate after injection of vitamin C. No alteration in the sedimentation rate was observed in the six controls after a period of five days. It seems that in a large number of cases a condition of hypovitaminosis C may influence the sedimentation rate. In the study of the effect of vitamin C on tuberculin skin sensitivity, sixteen patients were given a test with sufficient tuberculin to cause only a mild intradermic reaction; six of these patients were used as controls and received no cevitic acid. A distinct decrease in sensitivity to the same dose of tuberculin was found after the patient received cevitic acid, and those receiving cevitic acid responded less acutely to a retest with stronger tuberculin than did the controls. The average increase in the twenty-four hour erythema readings in the controls was 351 sq. mm., as contrasted with 76 sq. mm. increase in those receiving cevitic acid. At forty-eight hours the differences were not so marked. The observations indicate that in the presence of saturation with cevitic acid tuberculin sensitivity becomes less.

Relation Between Hypochromic Anemias and Iron Deficiency.—Brock uses the term "hypochromic anemia" to signify cases in which the blood picture is characterized by a low color index, hypochromia and microcytosis in the stained film, and a low mean corpuscular hemoglobin concentration. Examination of the facts of the distribution and exchange of iron in the body lends support to the view that the hypochromic anemias are the result of a state of iron deficiency in the body. The repeated association of hypochromic anemia with conditions that would be expected to lead to iron deficiency and the specific cure of the anemia with iron strongly favor the view that the hypochromic anemias are conditioned by a state of iron deficiency in the body. In considering the response of the blood to iron reaching the body by way of

the intestine in patients with hypochromic anemia, three selected cases are presented which illustrate different forms of response. Two cases, supported by a considerable body of corroborating evidence, suggest that large doses of iron which lead to the accumulation of a great excess of iron in the tissues are more effective in certain cases of hypochromic anemia than are smaller doses which allow of absorption of enough iron for hemoglobin formation. This mysterious efficacy of large doses is the baffling problem of the relation of the hypochromic anemias to iron deficiency. In some cases of hypochromic anemia, all that is required is sufficient iron by mouth to supply about 50 mg. daily for new hemoglobin and an undetermined but probably smaller amount for the replenishment of other tissues in the body which have become iron deficient. Another group of hypochromic anemias appears to respond only when iron is given in doses that lead to the accumulation in the body of amounts up to 200 mg. daily. There is at present no rational explanation of the necessity for such large doses. In resistant cases the dose should always be raised to the maximum before despairing of iron, and, since there are still many unexplained factors in the etiology of hypochromic anemia, a diet rich in protein and vitamins should always be insisted on.

Studies on Chemistry of Gaucher's Disease.—Thompson and Wright obtained portions of spleen from three cases of Gaucher's disease for chemical analysis. The study confirms Lieb's discovery that the essential pathologic change is a specific storage of kersasin. The distended "Gaucher cells" may be merely the result of an absorptive action of the histiocytes on an increased blood kersasin. This hypothesis, however, involving an increased blood kersasin, merely shifts the mystery of the origin of the kersasin back one stage. An alternative theory, based on the assumption that the galactolipins are possible important intermediaries in the antibody responses of the reticulo-endothelial system, suggests itself as the result of recent work on certain aspects of immunologic chemistry. In view of the work of Drury and his collaborators it is conceivable that the galactolipins, whose physiologic rôle in the body is at present unknown, may play a part in the production of antibodies by the reticulo-endothelial cells, and that Gaucher's disease may be some "inborn error of metabolism" of the mechanism responsible for some stage in the antibody production of the body, whereby excessive quantities of kersasin are synthesized and stored by the reticulo-endothelial cells. It appears also that certain substances, soluble in the lipid solvents and possibly related to the galactolipins, may play some part in the antigenic phenomena of both tissues and bacteria. Recent work on the chemistry of the tubercle bacillus also suggests that substances soluble in lipid solvents play an important part in the immunologic responses initiated by this organism. Whatever the etiology of the condition, Gaucher's disease affords to the chemist opportunities of study of a class of compounds the biologic function and origin of which are at present almost completely unknown.

Streptococcus Pyogenes in Air of Scarlet Fever Wards.—Brown and Allison experimented to isolate *Streptococcus pyogenes* from the air of scarlet fever wards. The method was to expose six blood agar plates to the air in each of four wards for three hours during three different periods of the twenty-four hours. The air was found to contain large numbers of hemolytic streptococci, most of which could be identified serologically. In one ward, in which the throats of the patients were swabbed, the serologic types identified were found to correspond to the types infecting patients in the ward. The degree of infection of the air with hemolytic streptococci showed considerable variation during the twenty-four hours. During the night, infection was absent or negligible; in the morning there was a steep rise followed by a slight fall in the degree of infection during the early afternoon. This variation is probably associated with the degree of air movement in the ward produced by the staff in the execution of their duties. Hemolytic streptococci were widespread in the ward air and the serologic types identified were not confined to the neighborhood of patients infected with a particular type. Though contact with infected hands, instruments, books and toys is probably of considerable importance in the transmission of infection with *Streptococcus pyogenes*, and though droplet transmission no doubt occurs as in other infections of the respiratory tract, the possibility of infection by the air cannot be dismissed, especially in multiple-bed wards in which patients infected with many different serologic types of hemolytic streptococci are being nursed.

Daily Water Consumption of Adults.—Magee determined the consumption of water and milk in the form of beverages, fluid foods and foods to which water or milk was added in cooking over a period of a week in two public assistance institutions containing 166 adults and three children. The consumption of water in the form of solid foods could not be estimated directly but was calculated from the results obtained from quantitative dietary studies of ten working-class families whose diet was adequate. The intake of water in solid food was calculated as 0.97 pint for men and 0.8 pint for women per head daily. Water formed in oxidation was assumed to be 300 cc. per head daily for men and 250 cc. for women. The total water consumed and formed in the body was therefore probably in the region of 4.93 pints (2,799 cc.) per head daily for men and 5.08 pints (2,885 cc.) per head daily for women. The water supplies of the institutions are soft and the amounts of calcium consumed in water were very small and are probably not of much nutritional significance. Hard waters are, however, probably of some importance as sources of calcium, especially when the diet otherwise is poor in this mineral. The amounts of milk consumed per head daily were in excess of

half a pint, 480 cc., and the amount of calcium consumed in the form of milk amounted to more than half the standard requirement for adults. The calcium intake in both institutions was probably adequate.

Endocrine Treatment of Functional Uterine Hemorrhage.—With a view of assessing the value of the use of gonadotropic and ovarian principles in the control of functional uterine hemorrhage, Jeffcoate discusses eighty cases and reviews those recorded in the literature. The conclusions are that the use of ovarian and gonadotropic substances in the treatment of functional uterine hemorrhage does not produce the brilliant results which some authors have claimed for it. Until the present views and theories regarding the ability of estrogen to produce luteinization are confined or clarified, there is no theoretical basis for the administration of this substance in the treatment of functional uterine hemorrhage, unless this bleeding is associated with endometrial atrophy or represents merely a menopausal menstrual irregularity or slight loss at the time of ovulation. The results obtained with corpus luteum appear as good as those accruing from the use of gonadotropic substances. The type of bleeding showing the best response is that which is nonovular in type, as in hemorrhagic metropathia. Pubescent and adolescent hemorrhage is very amenable to the treatment, but menopausal hemorrhage shows very little response. At puberty the bleeding is controlled in 80 per cent of cases, but of all patients suffering from functional uterine hemorrhage only 66 per cent derive real benefit. The treatment controls the bleeding only temporarily: any subsequent amenorrhea or return to the normal cycle merely represents the ordinary probabilities of such cases. A return of hemorrhage is not infrequent and the organotherapy of the relapse is more difficult than that of the original bleeding. Any ill effects of treatment are considered rare and constitute no real disadvantage to the practice of organotherapy in these cases.

New Factor in Production and Cure of Certain Macrocytic Anemias.—The work described by Wills and her collaborators suggests that at least two hematopoietic factors are present in all those extracts which are active both in true pernicious anemia in man—some only after incubation with normal gastric juice—and in the nutritional macrocytic anemia of the monkey. It is only when the principles concerned are obtained in a relatively pure form that their different action becomes clear. This monkey anemia appears to be due, in part

at least, to the lack of some other factor at present unidentified. It seems possible, however, that the two factors are concerned both in the monkey anemia and in pernicious anemia, and there is some evidence that this view is correct. For example, the more sustained response in the monkey to the crude extracts in comparison with the response to the more highly purified fractions, even when these are given in doses derived from far larger amounts of the parent substance than those used in the preparation of the cruder extracts, points in this direction. The fact that one monkey responded well to large doses of anahemin, when given immediately after the parenteral injection of the monkey fraction from yeast, also suggests that this principle is necessary for normal hematopoiesis in the monkey. The crude extracts may well contain both factors. If there is in the monkey suffering from macrocytic nutritional anemia a deficiency of both factors but a relatively greater lack of the new factor, the administration of the latter may activate the small supply of the liver principle still available in the body. The liver principle thus activated will cause an initial rise in the red cell count, which however will not be sustained when the small supply of the liver principle is exhausted. Accepting this explanation of the action of the new factor as correct, there might well be exceptional cases of pernicious anemia in which there is a deficiency not only in the liver principle contained in anahemin but also in the new hematopoietic factor. Such cases would either not respond to anahemin or make a poor unsustained response, but would respond to the cruder preparations. It is possible that the new factor is allied chemically to the hematopoietic substance earlier isolated by Cohn, McMeekin and Minot (1930) rather than to anahemin or hematopoietin.

Prognosis Following Recovery from Coronary Thrombosis.—Palmer studied the prognosis, with special regard to the influence of hypertension and cardiac enlargement, in 212 patients who survived an attack of coronary thrombosis by three months. More than one fourth were able to lead fairly active lives. In the remainder, angina of effort and dyspnea on exertion were the most important symptoms causing restriction of activity or invalidism, and these were operative in almost equal proportion. The active group lived longer following the attack than the restricted. The onset and incidence of angina after coronary thrombosis were not related to the height or changes in the height of the blood pressure or to the size of the heart. Angina of every grade of severity, including that compatible with a fairly active life, occurred in 39 per cent of the cases prior to the attack and in 58 per cent following it. The presence of subsequent angina did not affect the average duration of life. The incidence of dyspnea severe enough to cause restriction of activity followed closely the inci-

dence of cardiac enlargement. Congestive failure, which affected 13 per cent of the series, was found only in patients with enlarged hearts. Subsequent attacks of coronary thrombosis occurred in 28 per cent, about half of them during the first two years. The incidence of these attacks was unrelated to the height of the blood pressure but was somewhat higher in cases with enlargement than in those with hearts of normal size. About one fifth of these subsequent attacks were fatal. The duration of life following the attack averaged 4.2 years in sixty-five patients known to have died. Patients with hypertension appeared to have a somewhat more favorable outlook in this regard than those not affected similarly. The groups with cardiac enlargement and with congestive failure showed a slight reduction in the duration of life. Short summaries are given of the histories of eleven patients known to have lived for more than ten years following the attack. Blood pressure changes and the height of the blood pressure following recovery from an attack of coronary thrombosis are on the whole of little significance. The probability that following recovery from an attack of coronary thrombosis a patient will be able to lead a fairly active life is almost twice as great in those with normal sized hearts as in those with cardiac enlargement.

The Patient with a Lump in the Breast. P. J. Vivier.—p. 47.
Luxation of Innominate Bone. S. V. Humphries.—p. 53.

Diseases Transferable to Man from Domestic Animals.—Smith limits his discussion to diseases of domestic animals which are transferable to man. In most of these (rabies, anthrax, glanders, malignant edema, Malta fever, trichophyton skin diseases, platyhelminth and trichinella infection, paratyphoid, foot and mouth disease, psittacosis and pox) the danger can be averted by the adoption of simple precautionary measures. In others this is impossible without the help of the health department, which, through prescribed laws, reduces the danger to man of animal diseases and their diseased products to a minimum. In order to safeguard public health, the authorities must insist on having qualified men at the head of all slaughterhouses. This holds equally true for dairies and for the control of dairy cows. Regular examination of these cows should be one of the chief functions of a qualified man. Any milk from cows suffering from mastitis, enteritis, metritis, tuberculosis, and the like, should be condemned. The author points out that in most European countries all the food products derived from animals are under the strict supervision of qualified men. In this country, however, the municipalities have not even begun to enforce this supervision. It is only by the cooperation of medical and veterinary science that the public can be educated to demand their rights in this direction.

Comparison of Different Media for Growth of Tubercle Bacillus.—In ascertaining which was the simplest and most suitable medium for the enumeration of tubercle bacilli of the bovine or human type in tissue suspensions, Schwabacher found the highest proportion of colonies developed on a medium containing three parts of egg yolk and one part of saline solution, 5 per cent of glycerin being added for the human type. The replacement of saline solution by heart extract broth or liver extract was unfavorable. Experiments with egg white showed that this substance had no marked bactericidal action and that the failure of tubercle bacilli to grow in its presence was due to its high alkalinity. If this was neutralized, development of the bacilli occurred. The nutritive value, however, of neutral egg white was very much less than that of egg yolk. The addition of 10 per cent carbon

dioxide to the atmosphere in which the cultures were incubated was beneficial. The addition of 40 per cent oxygen had the opposite effect. For routine work a medium is recommended containing two parts of egg yolk to one of saline solution. If the medium is to be used for counting experiments in which discrete colonies are required, the proportion of yolk to saline solution should preferably be raised to 3:1.

Gastrectomy.—In 133 gastrectomies, Sénèque applied the gastrojejunal anastomosis practiced by Hofmeister-Finsterer by closing the upper gastric opening, but following a different technic. After ligating the pyloric and gastroduodenal ends as well as the pertinent vessels, he first performs resection of the duodenum. The closing takes place in three planes. The stomach is then resected between the upper third and the lower two thirds. All residual contents of the gastric stump are emptied. Finally the upper gastric opening is closed, likewise in three planes, one total and two seromembranous. The stomach is fixed backward and forward to the submesocolic opening, linen thread being used during the entire procedure. A simple infrahepatic drain is left for forty-eight hours. Local anesthesia was used in most cases. The older patients withstood the operation much easier than the relatively younger. In ulcers of the lesser curvature the author chose gastrectomy in preference to gastro-enterostomy, owing to the dangers of hemorrhage, persistence of pain and the possibility of neoplastic transformation. Of thirty-three cases, thirty were cured. Five cases of pyloric ulcer and forty of duodenal ulcer were all cured. Improvements were observed in thirteen cases of multiple ulcers, two pyloric stenoses from myomas and one medio-gastric stenosis from attempted suicide with formaldehyde. In ten cases of second gastrectomies and new enterostomoses, necessitated by ulcers persisting after the operation, the old anastomoses which were fixed to the mesocolon had to be freed again: the duodenal closure was resected and the stomach was sundered from the duodenum, and the jejunum was sutured; a gastrojejunal anastomosis was made after the resection of the stomach, and the stomach was fixed to the mesocolon. One of the ten died from strangulation of the small intestine.

Hepatobiliary Symptomatology of Constipation. G. Parturier.—p. 25.

*The Upper Cervical Point in Painful Hepatobiliary Syndromes. G. Parturier and Singer.—p. 51.

Upper Cervical Point in Painful Hepatobiliary Syndromes.—In the diagnosis of organic disturbances of the stomach and duodenum, Cade demonstrated in 1919 that a painful point at the upper right side of the neck is indicative of organopathy in the upper regions of the abdomen, notably of the liver and bile ducts. A similar point at the upper left side of the neck denotes disorder of the stomach and duodenum. Parturier and Singer have verified this point in all their 125 cases of hepatobiliary syndrome. It may be detected at a level with the third cervical vertebra. Posteriorly it is at the lower edge of the spinous process of the axis. Anteriorly it corresponds to the angle of the mandible. It may be reached by the palpating finger moving toward the internal part of the tubercle of the transverse process of the third cervical vertebra and behind the parotid to the vasculonervous bundle of the neck. This bundle escapes the pressure of the finger, which finally compresses the upper cervical ganglion. The point is not easily detected in adipose or short necked persons and the patient will have to assume various postures. The differential diagnosis includes cervical arthritis, rheumatism, osteitis, retropharyngeal abscess, pain from lymph nodes derived from angina or tonsillitis and finally the syndrome of the carotid sinus. Stimulation of the zone through external compression diminishes the number

of the heart beats and lowers the arterial pressure. Thus the authors often had the experience that the patient lost consciousness as a result of pressure with the examining finger. Pains in that zone could likewise be provoked in some cases through pressure on a diseased gallbladder, which disappeared with the amelioration of the abdominal symptoms.

Treatment of Anosmia with Insulin.—Berberich says that heretofore only the respiratory forms of anosmia have yielded to treatment, because it can be causal in that polyps, tumors, sinus suppurations and conchal hyperplasias are removed. In the essential anosmias the treatment was mostly symptomatic, strychnine being most frequently used either by local, oral or parenteral application. It acts by way of increasing the central irritability. Several other physical and pharmacologic methods act by exerting a trophic influence on the olfactory mucous membrane. The author resorted to insulin in the treatment of essential anosmias. The treatment is begun by giving three times each week from 10 to 15 units of insulin. If necessary, this dose is increased to from 20 to 25 units. Of ten patients with essential anosmia nine were cured, and of three with partial hyposmia two were cured. In case of relapse, the same treatment was again effective. Recently the author has given small doses of iodine in addition to the insulin. In attempting to explain the mode of action of insulin, he points out that it increases the nervous irritability and also exerts a trophic influence on the mucous membrane. Moreover, insulin increases the water binding capacity of the tissues and promotes the secretion and the blood perfusion of the mucous membrane. The latter action is increased by the simultaneous administration of iodine. The author says that Spiess produced similar effects with insulin in dry catarrhs of the nose and pharynx.

Induction of Local Immunity of Peritoneum.—Scalone administered injections of increasing doses of staphylococcus vaccine to rabbits. The injections were given in the preperitoneal connective tissue of the abdominal wall. The number of injections given to the animals in different lots varied from two to five. The animals were killed in good general condition at the end of the experiment. A gelatinous fluid was obtained from the peritoneal cavity in all cases. The amount of intraperitoneal fluid was not in relation to the number of injections given. The fluid has bactericidal action on staphylococcus but not on colon bacillus. The more or less intense bactericidal action was not in relation to the amount of intraperitoneal fluid but was in relation to the number of injections administered. The greater the amount of vaccine given to the animal, the more intense the bactericidal action of the fluid for staphylococcus. Because of the absence of phlogosis in the peritoneum and the lack of bactericidal action of the fluid on the colon bacillus, the author concludes that the vaccines produced local immunity of the peritoneum.

Nasal Mucosa in Diphtheria.—In his experiments on guinea-pigs, Vedova found that inoculation of diphtheria antitoxin in the nasal mucosa results in a condition of allergy to diphtheria which can be changed to immunity by stimulating the immunity processes. Immunity develops more easily from

subcutaneous inoculation than from nasal vaccination. Nasal inoculation results in simultaneous development of local and general immunity of the nasal mucosa and the skin, respectively.

Spleen Contracture and Splenomegaly in Tuberculosis.

—Bassi performed the epinephrine test in fifteen cases of splenomegaly in pulmonary tuberculosis. Contracture of the spleen took place in all cases within five and ten minutes after administration of an intramuscular injection of 1 mg. of epinephrine and lasted for about two hours. The less intense results from the test were those obtained in chronic forms of pulmonary tuberculosis. According to the author vasal hypotonia, with consequent congestion of the spleen, and cellular hyperplasia of the splenic pulp are the main pathogenic factors of tuberculous splenomegaly. Splenic sclerosis is frequent in cases of chronic pulmonary tuberculosis.

Gastric Functions in Pulmonary Tuberculosis.—Mazzuca found hypochlorhydria, hypo-acidity and hyposecretion in twenty-four patients suffering from gastric disturbances in pulmonary tuberculosis. The disturbances of the gastric functions were verified both in grave and in benign forms of the disease. The patients were placed in three groups and given intramuscular injections every other day as follows: Patients in the first group were given fifteen injections of a pepsin and sodium benzoate solution. (The author does not mention the dosage.) Patients in the second group were given twenty injections of pure pepsin (0.06 Gm. each for the first ten injections and 0.1 Gm. each for the last ten). Patients in the last group were given ten injections of a mixture made up of 0.04 Gm. of tryptophan and 0.08 Gm. of histidine. As a result of the treatments the amount of hydrochloric acid and the total acidity and pepsins in the gastric secretion improve. The gastric secretion, however, was never normal and the improvement induced by the treatment was temporary. The author calls attention to the fact that the effects of the treatment in gastric disturbances in pulmonary tuberculosis are different from those obtained from the same treatment in gastroduodenal ulcer.

Blood Transfusion in Treatment of Melena Neonatorum.—According to Franco, blood transfusion is indicated in genuine melena neonatorum. The procedure in new-born infants is not as difficult as it is believed when the injection is made in the internal saphenous vein with a blunt pointed needle. It is advisable to use pure blood because anticoagulants may cause shock. Blood from the father is administered. If it is not available, a relative of the infant may be the donor, if of the same blood group. The amount of blood administered varies between 30 and 45 cc. for the first injection. Transfusion is repeated after forty-eight hours in cases in which slight hemorrhage persists. No further treatment is necessary. In the four cases reported by the author, the infants were at full term. All treatments that are advised for controlling melena neonatorum failed. The patients were in extremely grave condition from the frequency and abundance of the hemorrhages and blood vomiting. There was intense pallor, hypothermia, weak pulse and cardiac beats and superficial respiration in all cases. Hemorrhages and blood vomiting were rapidly and permanently controlled with consequent recovery of the patients. The age of the patients now varies between 2 months and 2 years. The infants are all normal.

Kinetic Treatment of Gonococcal Arthritis of Knee Joint. L. Dubin.—p. 541.

Congestive Primary Splenomegaly.—According to Gravano, congestive primary splenomegaly is a chronic disease of slow evolution. It originates in disturbances of a venous system involving the portal and splenic veins (diffuse intraperiphlebitic form) or the splenic veins (cryptogenic form). The etiology of the former type is toxic or infectious, especially syphilis of the portal veins. That of the latter is unknown. The clinical latency of the disease is frequently interrupted by the production of gastro-intestinal hemorrhages, with consequent progressive anemia, and also ascites and fever. In certain cases the first attack is grave: The gastro-intestinal hemorrhages are severe and frequently repeated and there is intense anemia and ascites or rapid reproduction of ascites. The diagnosis is made by the clinical symptoms, the special type of splenomegaly and the intense positive results of the x-ray proof of the contraction of the spleen provoked by the injection of epinephrine. The prognosis of the disease is grave. It depends on the frequency and intensity of the gastro-intestinal hemorrhages, the intensity of the anemia and the degree of involvement of the liver in the pathologic process. The treatment varies with the form (cryptogenic or intraperiphlebitic) of the disease. In the cryptogenic form, splenectomy is indicated. It prevents further gastro-intestinal hemorrhages and controls anemia and further development of intraphlebitis of the portal and splenic veins. Splenectomy is contraindicated in the diffuse form of intraperiphlebitic congestive primary splenomegaly in which the pathologic process of the veins is due to an infection or intoxication. Medical treatment for controlling the infection or intoxication which exists in the given case is indicated. Two cases are reported by the author.

*Symptoms and Pathology of Synovioma. A. Fehr.—p. 88.

Tumors of Salivary Glands.—Histologic studies of sixty-two cases of neoplasms of the salivary glands, treated in the last twenty-five years in the Surgical Clinic of the University of Groningen, when compared with the clinical histories, convinced van Vierssen Trip that the clinical course of any given case, particularly with regard to the question of malignancy or benignancy, cannot be predicated on the histologic evidence alone. Not infrequently parotid tumors exhibit only one sign of malignancy, such as recurrence after removal. Recurrence is a common characteristic of the mixed tumors. One likewise observes tumors which do not break through the capsule and do not recur after removal, and occasionally one sees tumors which do not recur despite the fact that they presented the picture of an infiltrating growth. The behavior of a so-called benign salivary gland tumor cannot be predicted until a number of years after the operation. Mixed tumors presenting a simple histologic picture run a mild course. There was only one fatal outcome in the twenty-three cases of that type. Mixed tumors of a complicated histologic type, on the other hand, are much more malignant. In a group of twenty-three cases of that type, one proved fatal after a rapidly malignant course and two after a somewhat more prolonged course. Cylindromas were rare and their prognosis is dubious. A mixed tumor that runs a rapidly malignant course may be classed as carcinoma. Carcinomas of the parotid gland are epithelial tumors of manifest malignity. The borderline between a mixed tumor and a carcinoma is indefinite and varies with the observer's point of view. When the character of the mixed tumor is predominantly sarcomatous, the tumor may be designated as sarcoma. Three benign tumors were observed: a fibroma and two neurinomas.

Synovioma.—Fehr reports four cases of synovioma observed in Clairmont's clinic (Zurich) and reviews nineteen cases from the literature. The tumor originates in the synovial tissue of the joint capsule, tendon sheath or bursa. It is sarcomatous in nature and is characterized by slow growth. The most common localization is the knee joint. Despite its slow growth the tumor is definitely malignant, recurs after the widest excision and, without exception, causes death by metastasizing in the lungs. The tumor cells are resistant to the roentgen rays. Early amputation is indicated. Microscopic examination alone can establish the diagnosis. Characteristic sections present cavities lined with epithelioid cells. In the later stages and particularly in the recurrences and in metastases one finds ordinary sarcomatous spindle cells of which the origin from the synovial tissue is no longer recognizable.

Color Reaction of Cevitamic Acid.—Dietrich and Hundhausen point out that Risak observed that after exposure to sunlight melanogen is eliminated in the urine. However, Risak's observation could not be corroborated by others and the authors found that the urine of patients who had been treated with large quantities of cevitamic acid produced the same blue coloration that is observed during the elimination of melanogen. Further investigations proved that this reaction is no more specific for cevitamic acid than for pyrrole and indole bodies. It is elicited by many substances that effect reduction. Low values detected with methods of titration cannot be ascribed to vitamin C, but only higher values that appear after tolerance tests. A tolerance test method has been devised for the detection of a vitamin C deficit. The size of the deficit is expressed by the number of days the tolerance test has to be continued until this elimination has been reached. The authors employed the continuous vitamin C tolerance test in ten cases and compared the titrimetric determination in the urine with the outcome of the blue test. The test is made like Legal's test for acetone with sodium nitroprusside, sodium hydroxide and glacial acetic acid. The authors advise against a too concentrated sodium nitroprusside solution and suggest a hot saturated solution diluted to one third. The sodium hydroxide should be added drop by drop until a red color appears, which is due to creatinine. Then the glacial acetic acid is added in drops until a blue or a bluish green coloration appears. The blue is the more intense, the higher is the cevitamic acid concentration. In case of low concentration it disappears rapidly, particularly if too much acid is added. A tolerance test of eight days' duration failed to produce a positive blue test in only two of the ten patients. They were patients with severe exophthalmic goiter. In these patients the titration method likewise revealed no noticeable increase in the reduction capacity of the urine. They express the opinion that a greater intake of cevitamic acid might explain Risak's observation.

Vitamin B₁ and Carbohydrate Metabolism.—Tislowitz found that the parenteral administration of vitamin B₁ reduces the fasting blood sugar of normal rabbits and dogs and that the hyperglycemia of dogs after dextrose tolerance tests is likewise reduced following the administration of this vitamin. Moreover, the insulin hypoglycemia of normal dogs is greater in the animals that have been given vitamin B₁ than in the controls. It is assumed that vitamin B₁ has a point of attack either in the hypophysis or in the central nervous system. After pointing out that an insulin activating effect of vitamin B₁ has been assumed by others, the author suggests that the favorable action of certain vegetable diets on diabetes mellitus might, among other factors, be due to the content in certain vitamins. He thinks that in case of abuse of alcohol, particularly in delirium

tremens, vitamin B₁ might be helpful. Finally he suggests that by making slight changes in the structural formula of vitamin B₁ it may be possible to develop an antidiabetic remedy that is suitable for oral administration.

Carcinoma of Hypophysis in Boy.—Wentzler reports the clinical history of a boy, aged 9 years, in whom diabetes insipidus became manifest at the age of 5. The symptoms increased in severity, although there were occasional temporary improvements as the result of therapeutic measures. The boy died at the age of 9 and the necropsy revealed a carcinoma of the hypophysis with complete destruction of the posterior lobe and of the tuber cinereum. The anterior lobe of the hypophysis was normal, but the intermediate part of the hypophysis likewise exhibited considerable changes.

Protection Against Measles by Placental Extract.—Moeller reviews the history of the prophylactic value of placental extract in measles and then describes her own experiences with this type of prophylaxis in ninety-one children. In forty-four children between the ages of 3 months and 5 years, from 3 to 20 cc. of placental extract was injected between the fifth and the seventh day of incubation. Of these, only 20 per cent remained free from measles. Forty-seven children in another group were treated with from 10 to 15 cc. of placental extract on the second day of incubation and 97 per cent remained free from measles. The author thinks that, if correctly applied, placental extract provides an effective protection against measles. Placental extract is always available and, in case of early administration, it provides as much protection as convalescent serum and more than blood from adults. It represents a considerable advance in the prophylaxis of measles.

*Rational Roentgenotherapy of Acute Nonsuppurating Inflammations of Spinal Cord. P. Del Buono.—p. 251.

Roentgen Impairment of Parotid Gland.—In a patient who had received roentgen treatment on account of a carcinoma of the hypopharynx, Hermann observed at necropsy that the parotid gland on the irradiated side showed changes that were much more severe than those on the nonirradiated side. The questions arose whether the severe lipomatous degeneration of the parotid gland, particularly on the irradiated side, could have been caused by the roentgen irradiation, whether intensive irradiations of the side of the face would always cause an impairment of the salivary glands, and what differences regarding impairment exist between fractional irradiation without protraction and protracted fractional irradiation of the parotid gland. The author decided to investigate these problems in experiments on rabbits. On the whole, he gained the impression that the ray sensitivity of the parotid gland is slight in comparison to that of other organs. He believes that roentgen irradiation does not play any part in the lipomatous degeneration of the parotid gland and states that the impairments, which become manifest during the irradiations in the form of dryness of the mouth, painful swelling and facial edema, are only temporary, not permanent. To the third question no final answer is possible as yet, because, with few exceptions, there seems to be no difference between the results of the two modes of

irradiation. Accordingly, the author thinks that for economic reasons the merely fractional irradiation should be employed. Moreover, some of his own experiments indicate that fractional irradiation without protraction is less likely to cause changes than protracted fractional irradiation.

Roentgenotherapy of Inflammations of Spinal Cord.—Del Buono discusses roentgenotherapy in acute anterior poliomyelitis of children, in acute and chronic poliomyelitis of adults and in acute and chronic multiple sclerosis. He reaches the conclusion that roentgenotherapy is advisable in nonsuppurating, acute, inflammatory disorders of the spinal cord, because it produces better results than do other methods. The best results are obtained in acute anterior poliomyelitis of children, provided the treatment is begun early; that is, before the anatomic lesions of the spinal cord have become extensive. Favorable and lasting effects can be produced also in adults who have anterior poliomyelitis, acute multiple sclerosis or radiculomyelitis, but in these conditions also early beginning of the treatment is essential. In chronic multiple sclerosis, the effect of roentgenotherapy is slight. The improvement that may be noticeable after the first series of irradiations is not lasting and, after it disappears, the disease process advances unchecked. The technic of the irradiation is of minor importance, for favorable results have been obtained with various technics.

Histogenesis of Brenner's Ovarian Tumors.—Kleine sees the clinical significance of Brenner tumors in the fact that in spite of their "carcinoid" appearance they are always benign and that they are frequently mistaken for cancerous growths, particularly granulosa blastomas. He thinks that among the "cured" cases in the statistics on ovarian cancers there are probably many in which the so-called cancer had been a Brenner tumor. He emphasizes that Brenner tumors can be identified only histologically, not clinically. He differentiates two types: (1) solid Brenner tumors with and without the formation of microcysts and (2) Brenner tumors that are in the wall of large serous, but especially pseudomucinous, ovarian cystomas. Histologic examination reveals them as small complexes of tumor cells, frequently with irregular outlines, consisting of epithelium with round and spindle shaped nuclei. Generally the epithelium is undifferentiated, but it may be differentiated in pavement epithelium, serous epithelium and particularly mucous epithelium. The latter gives positive results when stained with mucicarmine and encloses microcysts in such a manner that the nuclei of the cylinder cells lining the cavity are on the side away from the lumen. This is an important differentiating characteristic from many folliculoid granulosa blastomas, in which the nuclei of the cell lining the cavity are turned toward the lumen. The author reports observations on five patients with Brenner tumors. In three cases the Brenner tumors concurred with pseudomucin cystomas, in one with serous cystoma and in the fifth with an epophoron cyst. In the latter case, two islands of Brenner epithelium, which could be recognized only microscopically, were found where the hilus passes into the mesosalpinx. The author also states that the histologic examination of 166 ovarian teratomas never revealed the presence of nests of Brenner epithelium. There are three possibilities for the histogenesis of Brenner epithelium: (1) from the surface epithelium of the ovary, (2) from the peritoneal epithelium (tubes and ligaments) and (3) from Wolff's epithelium (hilus). These modes of histogenesis explain the development of Brenner tumors near the ovarian surface and in the region of the hilus of the ovary; also the concurrence of Brenner tumors with pseudomucin cystomas or serous cystomas and the occurrence of so-called Werth's epithelial nodules in the tubes and in the broad uterine ligament.

Cholin Esterase Content of Blood of Umbilical Cord.

—Navratil points out that it has been proved that cholin esterase takes a special position among the esterases. Because this ferment regulates the formation as well as the cleavage of the acetylcholin that occurs in the tissues, it may be assumed that the significance of this ferment is closely connected with that of the highly active substrate. Since cholin esterase was first demonstrated in the cardiac muscle by Loewi and Navratil, a number of other investigators have studied its occurrence in the tissues and the blood. The author cites several methods by which the cholin esterase content can be determined and then reports his own studies. Immediately after the birth of the child, blood is withdrawn from the maternal arm vein and from the still pulsating umbilical cord. It was found that the maternal whole blood as well as its serum has a greater cholin esterase content than the umbilical blood and serum. The author admits that the process of delivery might have caused changes and thinks that control tests should be made before delivery or at its onset; that is, in the course of cesarean operations.

New Cerebropathologic Phenomenon.—Gerstmann describes a cerebral phenomenon that he observed in a woman, aged 33. The patient had headaches in the right upper parietal region, which area was also sensitive to pressure and percussion. Occasionally there were jacksonian attacks involving the contralateral (left) side of the body. These and other symptoms as well as the cephalographic observations and the course of the disease indicate a pathologic process in the retrocentral region of the cortex of the right cerebral hemisphere, chiefly the right upper parietal region. The extremely slow course suggests a benign tumor. The phenomenon to which the author wishes to call attention is the following: If black or colored glasses that are impervious to light are placed before the woman's open eyes and she is told to look in front of her without directing her eyes in any other direction, there develop rhythmic automatic movements in the anteroposterior direction. These movements cannot be voluntarily altered or suppressed by the woman. If she is standing, they involve the entire body; if she is sitting, only the trunk and head and, if the trunk is fixed, only the head. As soon as the patient closes her eyes, the movements cease, but, if she opens them again behind the impervious glasses, the movements reappear. The patient experiences the movements in the anterior direction as a forward traction that cannot be resisted; the backward movements the patient is unable to explain. Passive turning of the head in the direction contralateral to the cerebral focus intensifies the rhythmic oscillating movements and the patient utters an anxious cry in response to the intense sensation of falling toward the left. Passive movement of the head in the direction homolateral to the focus (that is, toward the right side) does not intensify the movements. Passive forward bending of the head and fixation in this position likewise intensify the rhythmic anteroposterior movements. Active movements of the head have similar effects. The body movements are accompanied by eye movements, but the latter take the opposite direction. Further studies proved that the movements can be elicited by placing before the eyes any uniformly colored (except white or gray) surface. However, as soon as fixation is effected by a definite outline or even by the prick of a pin in the otherwise uniform surface, the rhythmic body movements cease. Thus the movement phenomenon is elicited only if the eyes are open and fixation is impossible. This phenomenon gives rise to a number of questions that remain unexplained.

Gold Poisoning, Basophil Granulation and Eosinophilia.

—Hulst says that from May 1935 to May 1936 all patients with primary chronic polyarthritis who came to the Leiden clinic for rheumatic disorders were treated with intragluteal injections of a gold preparation. This gave him an opportunity to observe various forms of gold poisoning. The differences in the development and the occasionally rather sudden onset induced him to search for an objective sign that would indicate the approach of an intoxication. Since the literature contained reports about basophilic granulation of the erythrocytes after gold treatment, he investigated this manifestation. Of the fifty-one patients who had been treated with the gold preparation, only two never had the basophilic granulation of the erythrocytes. Of the forty-one who were examined before the gold injections were given, seven were found to have the basophilic granulation. Of the thirty-four patients who did not have the basophilic granulation, thirty-two developed it after the gold treatment had been continued for a shorter or longer period. The basophilic granulation formerly was regarded as a sign of degeneration, but recent observations seem to indicate that it is a regenerative process. The author cites instances in which chronic rheumatism occurred in patients who also had hypochromic anemia. The anemia proved refractory to iron and various other treatments but improved in the course of the gold therapy. The author gained the impression that the gold stimulates blood formation and causes the development of the basophilic granulation. He discusses the connection between gold therapy and eosinophilia. Many cases of gold poisoning were accompanied or preceded by an increase in the number of eosinophilic leukocytes. This increase subsides again as the signs of intoxication disappear. If eosinophilia appears in the course of gold therapy, it is advisable to interrupt the gold therapy until all signs of intoxication and the eosinophilia have disappeared.

Disturbances in Cardiac Rhythm in Tumors of Lung.

Formijne and Zuidema report the histories of nine patients with pulmonary carcinoma in whom they observed disturbances in the cardiac rhythm. The arrhythmias were all of the paroxysmal type. Fibrillation appears to be the most important of these disturbances of the cardiac rhythm. The authors observed it in four of their patients. In one patient cardiac flutter was observed and in another tachysystole. In the remaining three cases the character of the arrhythmia could not be definitely identified. In order to give information about the frequency of paroxysmal arrhythmia in patients with pulmonary tumors, the authors point out that, during the period in which they observed the nine pulmonary tumors with paroxysmal arrhythmia, they found thirty-three pulmonary tumors without it. They think that the paroxysmal development of the fibrillation and flutter may be regarded as characteristic for pulmonary tumors. In most of the cases the necropsy revealed that the neoplasm had invaded the pericardium or the musculature of the auricles.

Familial Congenital Fistula of Ear: Case. S. Söderlund.—p. 71.

Occurrence of Subcutaneous Lymph Nodes in Angle of Jaw and Anterior Jugular Vein in Domestic Cat. N. Westerholm and E. Lindholm.—p. 79.

Causes of Death Among Diabetic Patients.—Von Bonsdorff says that, from 1930 to 1936, 308 diabetic patients (117 men, 191 women) were treated in the Maria Hospital in Helsingfors, most of them several times; 110 were less than

50 years of age and 198 were more than 50. Of these, 120 have died, at an average age of 56.5 years; 50.8 per cent from arteriosclerotic cardiopathies and cerebral circulatory disturbances together with gangrene in the lower extremities, 15.8 per cent from infectious diseases, 14.3 per cent from diabetic coma, 10 per cent from tuberculosis and 5.8 per cent from malignant tumors. At least sixty-five cases of coma (in forty-five patients) were treated; of the seventeen deaths in this group, some might have been prevented if the cases had not been admitted too late because of mistaken diagnosis.

Anemia and Dysphagia or Plummer-Vinson's Syndrome.—Schauman reports three typical cases of the disease. A fourth case presented the characteristic clinical picture of Plummer-Vinson's syndrome and no signs of cancer, but the patient's death five months after discharge was perhaps due to cancer of the stomach. The possibility of a connection between the Plummer-Vinson syndrome and the cancer is discussed.

Calcifications in Veins. A. Eldahl.—p. 108.

Histology of Neurinomas.—Lindenov says that in his case of intraperitoneal neurinoma in a man, aged 45, an accidental observation at necropsy, the reticular parts of the tissue containing nuclei resembled the form of neurinoma tissue described by Antoni as type B, and the diagnosis was further supported by the content of colloid masses. While the capsule and the neurinomatous tissue were not clearly separate, the former appeared so definitely as a capsule that the fibrous tissue was regarded as drawn into the proliferation and not as a constituent of the tumor, which is ascribed to germs broken off in fetal life from some preliminary stage of the splenic plexus.

Cevitamic Acid and Its Keeping Qualities in Aqueous Solution with Presence of Sodium Chloride: Preliminary Report. F. Westergaard. p. 134.

Formol-Gel Reaction and Other Globulin Reactions.—Bing performs the formol-gel reaction by adding two drops of solution of formaldehyde to 1 cc. of serum allowed to stand at laboratory temperature for three hours. He finds the test positive in disturbances with considerable hyperglobulinemia, in Denmark primarily occurring in cases of multiple myelomas or chronic infectious disease. In his material it was positive in fourteen cases of myeloma, in several peculiar cases of sepsis lenta, and in some instances of specific infections and hepatic disorders. There were rapidly positive formol-gel reaction and considerable hyperglobulinemia with resulting hyperproteinemia in one case of lymphatic leukemia and one of Schönlein-Henoch's purpura, diseases in which these changes had not previously been found. In 3,697 Danish serums only about 2 per cent gave a positive reaction. Other globulin reactions are briefly described.

*Contribution to Question of Heredity in Congenital Stenosis of Pylorus. B. Fabricius and P. Vogt-Møller.—p. 166.

Variations in Permeability of Red Blood Corpuscles.—Bang and Ørskov express the permeability of the red blood corpuscles to dextrose by the minute constant computed according to Pick's law. They state that increase of the dextrose concentration in the suspension fluid from 0.58 per cent to 1.16 per cent reduces the permeability two and one-half times. Their tests were carried out after the blood had been allowed to stand for four hours or more. In twelve normal persons the average minute constant was 0.27. This was also the

average value in nine cases of anemia due to hemorrhage, the maximum being 0.39, but in four cases of untreated pernicious anemia the minute constant varied from 0.42 to 1.14 and the highest and the lowest values occurred in cases with about the same degree of anemia. In two out of six other cases of pernicious anemia tested some time after the start of treatment the minute constant was normal; in four it varied from 0.46 to 0.81; here also there was no clear parallel between the degree of anemia and the permeability. During treatment, normal values were attained while the anemia was still marked. Investigations in patients with other disturbances revealed a minute constant under 0.40, and usually normal, in most cases. Normal values seen in two cases of leukemia are considered especially interesting. In a case of extensive osteitis deformans and in one of diabetes the minute constant was more than 0.40. Tests of the permeability to malonamid and tiourin substance gave results similar to those with dextrose. The permeability to glycerin was normal in pernicious anemia and not affected by specific treatment.

Heredity in Congenital Stenosis of Pylorus.—Fabricius and Vogt-Møller state that, while congenital pyloric stenosis is mentioned in the literature as a familial disorder, apparently no cases have been reported corresponding to the four reported by them in siblings who are a mother's entire family but the oldest of whom is the half sister of the other three.

Hematuria After Tonsillectomy and Adenotomy. H. Rasmussen.—p. 191.

Treatment of Encephalitis.—Levison says that he has attained good results in chronic epidemic encephalitis and other chronic infectious diseases of the central nervous system of unknown cause, also in multiple sclerosis by a combination of arsenic and bismuth preparations which, although not really specific, he terms "specific treatment," together with omnadin (or omnol), perhaps metallosal, and diaphoretic treatment. For relief of symptoms the usual agents have been employed—phenylethylbarbituric acid, scopolamine, atropine, coniine and so on, and finally orthopedic and in rare cases surgical treatment. The treatment is protracted and to be continued after the symptoms have disappeared. In his opinion an unfavorable prognosis is often assigned to chronic epidemic encephalitis because of the grave, rigid and parkinsonian cases, which however are not numerous. On admission of 122 cases grave parkinsonism was found in two, moderately grave in five and mild in two; i. e., in 5.7 per cent. The many mild cases, also those with slight parkinsonian syndrome, the neurasthenia-like forms and even the marked hyperkinetic forms may have an excellent prognosis.

Posttraumatic Arteriospasm in Fingers.—Mikkelsen asserts that in a number of cases diagnosed as traumatic neuroses there is in reality a posttraumatic arteriospasm or other disorder in the sympathetic nervous system. In arteriospasm the predominating subjective symptoms are sensation of cold and pain from cold; there are also pain on movement, hypalgesia and trophic disturbances. With arteriospasm limited to one finger he is reluctant to undertake extirpation of the third cervical ganglion and for the last year and a half has treated such arteriospasm conservatively by bandaging the finger for a long time. Complete recovery occurred in the six patients treated with finger splints and arm slings for from two weeks to three months. Two patients with arteriospasm in the whole hand after a Colles fracture were also successfully treated by bandaging. The hyperalgesic form, with paresthesias, appears only in the fingers and only after grave lesions. Half a year ago the author began to inject 1 per cent procaine hydrochloride-epinephrine in the finger or finger stump. Fourteen patients have now been treated by this method, with complete recovery in eight, almost complete recovery in five and no change in one. He emphasizes that the injection, which is painful, must be made in the tender part of the finger or finger stump and in the entire cyanotic field.

THE PROBLEM OF TUBERCULOSIS

FROM THE GENERAL PRACTITIONER'S
POINT OF VIEW

B. P. POTTER, M.D.

SECAUCUS, N. J.

The subject of tuberculosis, more specifically pulmonary tuberculosis, is talked and written about so often these days that one feels apologetic when adding another paper to the already voluminous literature. Yet there are certain features of the subject of special interest to the general practitioner that require emphasis and other points of importance to all interested in preventing the more or less permanently damaging and disabling phases of the disease that call for reevaluation. In addition, I shall attempt to outline a workable program in which all physicians can and should partake and that embraces methods by which it may be hoped in the next several generations not only to reduce the morbidity very appreciably from its present level but also to give the profession just reason to feel that such reduction might be directly linked with its efforts.

In the desire to emphasize the necessity and importance of the public health activities of both lay and medical organizations especially interested in the problems of tuberculosis, one not infrequently leaves a misleading impression with the public and the general practitioner as to the real situation. Thus every one is familiar with the figures often repeated showing the remarkable reduction in the death rate from tuberculosis in the past quarter of a century and with the comparative figures indicating that tuberculosis now has taken seventh place as a general cause of death. While the reduction in the number of frank clinical cases of tuberculosis is less often mentioned, it is a fact, nevertheless, that the decline in the morbidity rate has kept pace with the reduction in mortality.¹ What fails to be stressed or perhaps, I should rather say, is not kept foremost before the public and the medical profession is the fact that between the ages of 15 and 35 tuberculosis accounts for more deaths in the general population than does any other disease, and that at least 500,000, if not more, individuals are known to have clinical tuberculosis. This is the real problem; and it is a serious one, especially when it is remembered that hospital beds are available for only about 15 to 20 per cent of those afflicted. From the last statement it is obvious that there are an ever present large number of carriers who serve to plant the seeds for a new generation of tuberculous individuals.

Now how shall this situation be coped with? The lack of specific immunizing or therapeutic agents, the

peculiar development of the primary infection and its almost universal occurrence as adult age is approached, the effect of the first infection on subsequent superinfections and the clinical behavior of a second or adult infection make the problem of attack on this disease wholly different in most respects from that encountered in other contagious diseases, such as diphtheria and scarlet fever.

From a knowledge of the biologic characteristics of the tubercle bacillus and the pathogenesis of tuberculosis it is obvious that accidental infections cannot entirely be avoided. In spite of all activities for the prevention of infections, at least 40 to 60 per cent of the population show evidence of its presence when maturity is reached. Even if these accidental infections were preventable it is debatable whether it would be advisable to undertake such a course in view of the concept held by the majority of workers that the immunity which results exerts a favorable influence on subsequent superinfections.

Segregation of carriers remains the only measure of approach common to all contagious diseases. But even here there is a double limitation. In the first place, as has been already stated, hospitalization is available for only 15 to 20 per cent of those afflicted. In the second place, because of the chronicity of the disease, isolation is often impracticable. On the other hand there is unquestionable evidence indicating that in an appreciable number of adults with clinical tuberculosis a history of contact, usually of continuous and prolonged type, is obtained.

Table 1 is self explanatory but it reveals only diagnosed contacts. It must be assumed that the number would rise appreciably if those in the family presenting asymptomatic tuberculous lesions were carefully studied. Furthermore, as shown by Weintraub² in a study of 1,046 children under 15 years of age of whom 547 were contacts and 499 noncontacts, tuberculosis of the adult type was found in eleven of the contacts but in not a single instance was it encountered in the noncontacts. It seems that, barring for the present moment the question of the probable effect of unfavorable economic conditions, it may be said that the problem resolves itself to the avoidance of infections with large doses of tubercle bacilli by early discovery of frank cases of tuberculosis and by the application of appropriate therapeutic management of the abacillary cases not necessarily under isolated conditions but of all open cases under segregation.

The early diagnosis campaign is, to say the least, ambiguous. If by it one means to imply that the physician should detect under ordinary circumstances tuberculosis in its early stages more often than he does, one demands of him what past experience has shown is not

possible. It is the universal experience of competent internists and phthisiologists that physical signs in minimal and early moderately advanced disease may be entirely wanting or so indistinct as to give no clue of the presence of pulmonary changes. Added to this fact is the observation that complaints, objective or subjective, often parallel the physical signs in the latency

TABLE 1.—History of Contact in One Hundred Consecutive Patients

Sex	Number	Contacts	Noncontacts

of their appearance. In other words, assuming that the patient consults the physician soon after symptoms manifest themselves and that the physician in turn is alert enough to think of the presence of tuberculosis, the disease by that time has already passed its early phase in most cases.

TABLE 2.—Interval Between Appearance of Symptoms and Visit to Physician

Number.....	Sex		Total
	Male	Female	
1 month.....	15	32	47
1 to 2 months.....	6	5	11
3 months.....	5	1	6
4 months.....	5	4	9
5 months.....	1	2	3
6 months.....	2	0	2

2 to 3 years.....	4	0	4
3 to 4 years.....	3	0	3
4 to 5 years.....	1	0	1
5 to 6 years.....	1	0	1

This is well illustrated in tables 2, 3 and 4, in which 100 cases are analyzed with regard to these points. It will be seen that 64 per cent of the patients consulted a physician within three months after the appearance of symptoms and that in 76 per cent of these a positive diagnosis was made by the family physician within three months after the first visit of the patient.

TABLE 3.—Interval Between First Visit to Physician and Positive Diagnosis

6 to 7 years.....	0	1	1

Yet, as is shown in table 4, far advanced disease was already present in 84 per cent when diagnosed. It appears, therefore, that the detection of the disease in its earlier stages by awaiting the development of symptoms is not possible because of the insidiousness of onset.

If, on the other hand, early diagnosis signifies that the physician should detect tuberculosis early after the patient consults him, it may be proudly said that this is exactly what happens in the vast majority of instances, as already pointed out. It is apparent, therefore, that the finding of frank cases of tuberculosis can be enhanced only by methods of greater precision and by the utilization of a more extensive case finding program. The wider use of the x-rays and less attention to physical examinations in all patients who consult physicians for symptoms that even in the remotest way suggest the possibility or probability of tuberculosis will be a great step forward. I need merely cite the following case to illustrate this point:

CASE 1.—J. O., a white woman, aged 23, a housewife, was perfectly well until September 1936, when she noted a few specks of blood in her sputum on one occasion. At her hus-

TABLE 4.—Classification of Patients on Admission to Clinic

Total.....	100	2	14	84

band's insistence she visited a physician, who found nothing of significance in the general examination but was attracted to the lungs by a few râles in the paravertebral region of the left midchest. He insisted that an x-ray examination be made to rule out any pulmonary pathologic condition as a cause for the streaked sputum. The x-ray film shown in figure 1 reveals a soft walled cavity immediately off the left cardiac border in the region of the second and third interspaces. Note also a Ranke complex in the right lung. Sputum was found to be positive for tubercle bacilli. The left lung was subsequently collapsed and at no time was the patient in the sanatorium. She is now doing housework once more.

The physician falls short of his duty if he stops here. He must exert all the influence that his personality and the confidence of the patient in him command to examine all contacts or arrange for free examination, when economic conditions forbid otherwise. In this way one

TABLE 5.—Number of Known Familial Contacts in Thirty-Three Patients

Sex	Number	Number of Contacts		
		1	2	3

Female.....	17	11	4	2
Total.....	33	23	6	4

often surprisingly finds other tuberculous individuals not suspected and not rarely discovers "familial nests" of several persons, as can be seen by referring to table 5, which reflects the usual observations. I have at the present time under my supervision several patients in whose families there are from four to six tuberculous members.

While studies along the line just indicated of those who present themselves for examination are bound to disclose an increased number of diseased, there still remains an unknown number of sources that will not be reached unless the plan of attack is carried a step further—and it is here that a more extensive case finding program enters into consideration. I refer to those individuals who style themselves "cigaret coughers" or sufferers of "chronic bronchial trouble" and to the vast army of persons with quiescent lesions, in not a few of

whom the sputum is laden with tubercle bacilli. They form the more dangerous group, for they go about innocently for indefinite periods of time until symptoms of import appear, without any regard to the disposal of the sputum or to the application of other precautionary measures. These persons are true carriers, who can be discovered only by such measures as are about to be discussed.

1. The work of Lees³ with the students at the University of Pennsylvania not only is of great epidemiologic interest but also demonstrates how asymptomatic lesions can be discovered before they progress to the more advanced stage. As stated by him, the program embraces the following:

The tuberculin test is applied to all new students as a part of the entrance physical examination and chest x-rays are provided for the positive reactors. By this procedure all cases of pulmonary tuberculosis in the incoming group should be detected. If a student is found to have the disease in an advanced or infectious stage, he is advised to undergo treatment at once, thus eliminating from the student body a source of real danger. Students presenting minimal, healed or inactive lesions

an interval of six months following negative chest films; one case after eighteen months; three cases after twenty months; and three cases after an interval of two years. Only one of this group of ten students was symptom free and eight of the ten have received sanatorium treatment. In no case was there a history of symptoms having been present for a period as long as eight weeks. It should be emphasized that in the majority of such cases the pulmonary lesion has become decidedly dangerous in character and extent by the time definite symptoms have made their appearance.

Similar studies are in progress in many schools of medicine and nursing with similar results. Diehl and Myers⁴ have included in their studies faculty members and all employees of the school. This is a very important addition, for not rarely a teacher may be found to have an open case of tuberculosis (case 2).

CASE 2.—Miss I. G., aged 23, a school teacher, had been complaining of loss of weight and occasional cramps in the abdomen following meals for about two months before she consulted a physician. After examination the family physician referred her to a "nose and throat specialist," who advised a submucous resection. This was done, and except for slow healing of the wound the patient had an uneventful convalescence and returned

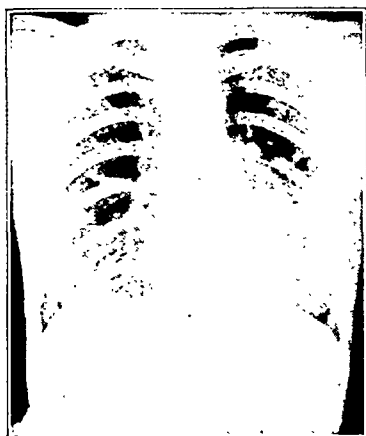

Fig. 1 (case 1).—A soft walled cavity immediately off the left cardiac border in the region of the second and third interspaces. Note also the complex of Ranke in the right lung.

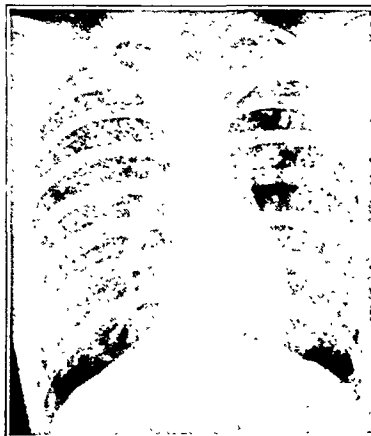

Fig. 2 (case 2).—Note extensive fine mottled infiltrate throughout both lungs, with multiple cavities in the left upper lobe.

Fig. 3 (case 3).—Appearance on admission to the hospital. There is shown a fibrocalcific lesion in the left upper lobe with cavity formation, and a productive stringy infiltrate in the right upper lobe.

may often be kept under close observation and their activities limited as may be indicated through careful study of each individual case.

In the same paper further very significant conclusions are recorded:

Recent statistics reveal the fact that tuberculosis mortality in males 20 to 24 years of age is more than double the rate which prevails in the age group 15-19 years. The sharpest rise in the incidence of tuberculosis occurs between the ages of 14-24. Certainly the problem as we have found it at the University of Pennsylvania is in keeping with the above. Most of our cases are found among upper classmen and especially those students enrolled in schools on the graduate level. We feel therefore that our program, to be most effective, must be extended so as to provide annual chest x-rays for all members of our student body who react to tuberculin. We realize that a negative chest x-ray obtained at the time of the student's entrance to the university is by no means a guaranty that he will remain free of tuberculosis for the duration of his college course. This fact is emphasized by our observation of the development of tuberculosis in a group of students who had previously been shown by x-ray to be entirely free of the disease. One student presented a definite tuberculous infiltration five months after a negative chest x-ray. Slight but suggestive symptoms were present. Two cases had been discovered after

home ten days thereafter. Several weeks later she returned to the specialist stating that she had noted no improvement and on one occasion had blood streaked sputum. Another examination was made and a tonsillectomy advised; that operation too was done. Following the tonsillectomy she began running a febrile course, remained in the hospital for about a week and then returned home, where she stayed in bed because of fever and marked fatigue. On bed rest, fever subsided except for a slight rise in the late afternoon. Several weeks later she began to have intermittent attacks of abdominal cramps and diarrhea, for which she again consulted her family physician, who gave her electrical treatment to the abdomen; a treatment which was continued for some time but without improvement.

At this time I saw and examined her. She was malnourished, and physical signs pointed to a definite pathologic condition in the upper lobes of both lungs. The sputum was positive and a roentgenogram of the chest as shown in figure 2 revealed extensive disseminated tuberculosis with multiple cavities in the left upper lobe.

At first one may wonder what this had to do with the general practitioner, but a second thought will convince one that without the family physician this work cannot be fully successful. It is to him that the parents or guardians often turn for advice as to the necessity and safety of such studies and the practicality of the cost

3. Lees, H. D.: Tuberculosis as a Student Health Problem, presented before the American Student Health Association at its annual meeting in New York City, Dec. 28, 1934.

4. Diehl, H. S., and Myers, J. A.: Tuberculosis in College Students, read before the Sociological Section of the Thirty-Second Annual Meeting of the National Tuberculosis Association at New Orleans, April 1936.

involved. Furthermore, to assure best results, school authorities must solicit the aid of the family physician if possible contacts are to be looked for at home. Unless the general practitioner is convinced of the importance of such studies no public health scheme, as the one just cited, can be of lasting or even of immediate benefit.

2. Similar studies are in vogue in some commercial organizations. I refer particularly to those of the Metropolitan Life Insurance Company, whose employees are periodically examined and whose applicants for employment have, in addition to a general physical examination, a thorough inspection of the lungs. The following case convincingly illustrates how industry can be of aid in a case finding program:

CASE 3.—A. L., a white woman, aged 34, a housewife, was rejected in August 1933 when she applied for a position at the Metropolitan Life Insurance Company. To discover the reason for this she consulted her physician, who said that she had "low blood pressure and irregular heart." In November the Metropolitan Life Insurance Company made an x-ray examination and pronounced her tuberculous. She was referred to Bellevue Hospital, where a left phrenicectomy was performed.

Fig. 4 (case 3).—Partial pneumothorax of left lung and complete collapse of cavity.

Fig. 5 (case 4).—Appearance in 1931, showing calcified nodes in the left hilus.

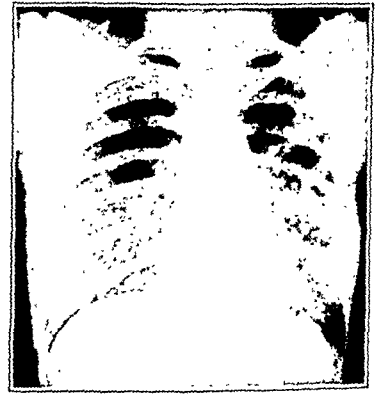

Fig. 6 (case 4).—Appearance in 1935 just before admission to the hospital: exudative cavernous process in left upper lobe.

The patient remained there for four months, leaving of her own will. In April 1934 she returned to Bellevue Hospital because she was getting hypogastric pains. Barium sulfate meal examinations were done with negative results. She then consulted our clinic in November and was subsequently admitted to the sanatorium. Figure 3 shows the x-ray film made on admission to the hospital. There is seen a fibrocalfic lesion in the left upper lobe and a cavity extending from the first into the second interspace. A stringy productive infiltrate is present in the right upper lobe. Pneumothorax was induced, resulting in an effective collapse, as can be seen in figure 4.

This is only one case of many in which tuberculosis has thus been detected. Recently other large industrial concerns have adopted this plan.

It is obvious that in the last analysis responsibility of convincing these individuals of the necessity for early treatment and of the importance of checking all contacts rests with the family physician. It becomes his duty to serve as a unit in the general scheme of educating the public, and particularly the business men of his community, of the advisability of such endeavors.

The universal adoption of careful examination of the students and employees of schools of higher education and of applicants and employees of large industrial plants points to a very potent method by which the unknown cases of tuberculosis and the sources of their infection can be found.

It is appropriate at this point to consider the value of the wholesale tuberculin testing of children as a case finding procedure. Even the most ardent supporters of this method admit its uselessness in grade school children. Attention has therefore been shifted to the high school groups, but even here there is controversy. Let us examine the facts and try to come to some tentative conclusions with regard to the attitude that should be taken. In the vast majority of instances children in various high schools were tuberculin tested and roentgenograms of the chest were taken of the positive reactors. Those who failed to react to tuberculin were properly considered to have had no infection but improperly dismissed from further consideration. Even the positive reactors, unless they showed active primary or secondary infections, were not always followed further.

What has been the result? Sporadic cases of tuberculous disease have been recorded, but, on the whole, in such an insignificant number of thousands on thousands examined as to cast serious doubt in the minds of the original advocates of this procedure as to its practicality.

In other words, it is being questioned whether those entrusted with public or private funds that could be used to more profitable advantage are justified in utilizing them in consideration of the meager returns.

There are, however, other points to be held in mind. First, of what lasting advantage is the discovery of tuberculous disease in the child unless it is utilized to find the source of infection?

Second, is one justified to assume in the light of our knowledge as to the pathogenesis of tuberculosis that the positive reactor without any evident tuberculous disease may be dismissed from further observation at least through adolescence?

Third, is it to be taken that a child failing to react to tuberculin at any given time will not shortly thereafter become infected and subsequently become exposed to the possibilities of his positive reacting brother?

It is these questions that have been raised by some county medical societies which have been asked to approve mass tuberculin testing of children. In fact, approval would not be given in certain instances unless the program would include periodic follow-up examinations of positive reactors and repeated tuberculin testing at various intervals of the negative reactors.

But even under these provisions recent work seems to cast doubt on the plausibility of the universal applica-

tion of mass tuberculin testing methods. Most convincing is the paper by Weintraub,² reference to which has already been made. The following two cases unmistakably confirm his report:

CASE 4.—A white girl, aged 14 years, was admitted to the sanatorium in December 1935. The past history was significant in that both the grandfather and father had died of tuberculosis, the former in January 1935 and the latter ten years before. She was followed as a contact case in the tuberculosis clinic, where an x-ray film (fig. 5) taken in January 1931 revealed calcified nodes in the left hilus. No further x-ray films were taken and she got along well until January 1935 at about the time of the death of her grandfather, when she experienced the sudden onset of fever, cough and high temperature. She was immediately put to bed and remained there for one month under a physician's care. The temperature remained elevated for several days and the condition was diagnosed influenza. When she got up from bed the cough had ceased and she felt fairly well except for a persistent feeling of weakness. This finally disappeared and slight increase in weight was noted. She returned to school, making monthly visits to the clinic. One month before admission to the sanatorium she was overtaken by a sharp pain in the left side of the chest, which lasted throughout the night. This was followed by productive cough. An x-ray film was then taken and, as seen in figure 6, revealed

x-ray film taken after the onset of symptoms, reveals a soft infiltrate in the apex extending into the first and second interspaces of the left upper lobe and a cavity in the region of the first interspace. At the present time the patient is in the sanatorium and on bed rest is making favorable progress, as is shown in figure 12.

Both of these patients were in school during their infective stage and would no doubt have been found earlier if a tuberculin test survey had been made in those schools. On the other hand there remains the fact that, if they had been followed more closely as contacts, their tuberculosis would have been detected without such a survey and properly managed sooner.

It seems, therefore, that there is no justification in diverting needed funds and the attention of the public and the medical profession from the program followed by schools of higher education and by some of the large industrial plants, which is more practical and which in the long run will be productive of the results desired. I do not wish, however, to be understood to go on record entirely against mass tuberculin testing. I feel that it has its place as a supplement to or as a poorer substitute for the program just outlined, provided the

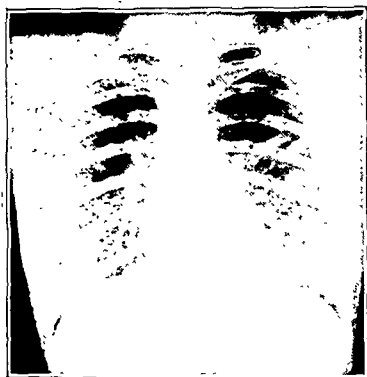

Fig. 7 (case 4).—Note partial collapse of the left lung, with complete obliteration of the cavity.

Fig. 8 (case 5).—Appearance in 1930 when the patient was examined as a contact. Note accentuation of the pulmonary markings extending from the upper pole of the left hilus toward the apex and the mottled infiltrate along the apical branch of the bronchus of the upper lobe.

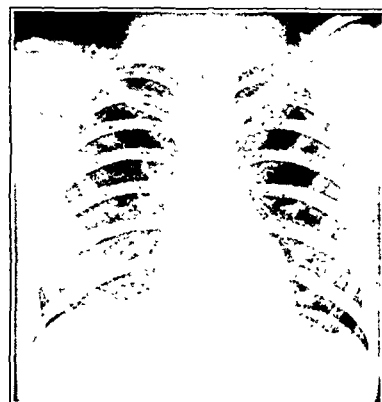

Fig. 9 (case 5).—Appearance in 1934, showing a homogeneous dense infiltrate in the left apex in the region where there was only a mottled infiltrate in the film of 1930.

an exudative ulcerative process in the left upper lobe. On admission to the sanatorium the sputum was found positive and pneumothorax was induced on the left side. Figure 7 shows an effective collapse of the left lung. The patient is now ambulatory and back in school.

CASE 5.—C. G., a white girl, aged 14 years, and her sisters and brothers were examined at the tuberculosis clinic after the death of their mother of tuberculosis in 1930. They were told that they were infected but were allowed to continue at school and do their routine work. In August 1934, following her monthly examination, she was told that her condition was worse and she was sent to the state sanatorium. At that time she was symptom free. While at the sanatorium she was not confined to bed at any time and continued to go to school. She was allowed complete freedom and remained symptom free. In 1935 a tonsillectomy was performed and she was finally discharged from the sanatorium in January 1935 and referred to the tuberculosis clinic in her community. She felt well until February 1936, when chills, fever and loss of appetite developed and she became easily fatigued; this was followed by several hemorrhages. A review of the x-ray films shown in figures 8, 9, 10 and 11 shows that no x-ray examination was made between 1930 and 1934, by which time she already had an infiltrate in the left apex. After discharge from the state sanatorium a small cavity is noted in the left first interspace, as revealed in figure 10. Finally figure 11, representing an

community can afford it and provided, too, that it is used to find the source of infection. It should also be occasionally utilized when tuberculosis is discovered in a pupil. Under such conditions it would be only natural to determine the status of the other pupils just as would be done if a definite case of diphtheria had been found.

Up to this point I have attempted to indicate the rôle of the practitioner in the examination of contacts of the known cases of tuberculosis and the part he must play as an educator in the larger plan of case finding of individuals with asymptomatic tuberculosis. This, however, is not sufficient—his influence must be extended to include the proper management of the open case, with two things in mind: first, to segregate the patients and, second, to convert the sputum abacillary by early treatment at home or in the office of those in whom this is possible. In this respect it has been my experience that the practitioner often temporizes or else divorces himself from the case by referring it to a tuberculosis clinic. The former attitude is often due to lack of acquaintance with the modern treatment of pulmonary tuberculosis. The physician must realize

that the earlier appropriate therapeutic measures are applied the sooner the patient ceases to be a menace, and the prognosis becomes increasingly more favorable in many instances.

It is not my purpose to go into details as to the treatment of pulmonary tuberculosis and its complications at this time. This has been done elsewhere.⁵ It is important, however, to stress that the family physician should be conversant with the recent concepts on the treatment of pulmonary tuberculosis. He should know that, while the infiltrative forms of this disease with negative sputum often respond to the hygienic bed rest regimen, more active treatment should be entertained at once in all cases in which cavitation is present. Even though it is true that certain types of small cavities not infrequently become obliterated without collapse therapy, it is best for the practitioner to take the attitude that, by and large, such results in cavernous tuberculosis are the exception rather than the rule.

With these principles as a basis, the practitioner can make himself useful in many respects to the patient and the community. He should aid the public health agencies in selecting those individuals who, because of poor home conditions, because of severity of the disease, or

great bearing on the control of tuberculosis. This sentiment is well expressed by Max Pinner,⁶ who says:

One may well question whether the insanitary living conditions per se are not a most significant condition to make reinfection, be it endogenous or exogenous, possible. In other words, many persons may not and do not develop clinical disease though they are exposed to open tuberculosis; but if the strain of slum conditions or intercurrent disease is brought to bear on the individual, he may succumb to his endogenous or exogenous sources of infection. For all practical purposes the problem resolves itself into the question whether living conditions in the widest sense of the word or whether exposure to an exogenous source of infection is the dominant factor in producing postprimary disease.

There is no doubt in my mind that poor economic conditions with the resultant unhygienic home surroundings play an important part in adding to the number of tuberculous persons. Observations on the patients in our outpatient department indicate that the number of readmissions are greater among those who return from adverse home conditions.

It seems to me that it is not sufficient merely to admit the existence of an economic factor in the development of frank cases of tuberculosis. One should, as one does in certain industrial diseases, not only point out the

Fig. 10 (case 5).—Appearance after discharge from the state sanatorium. A remarkable resolution of the dense infiltrate is seen in the left apex, but a small cavity is noted beneath the second anterior rib surrounded by an exudative infiltrate.

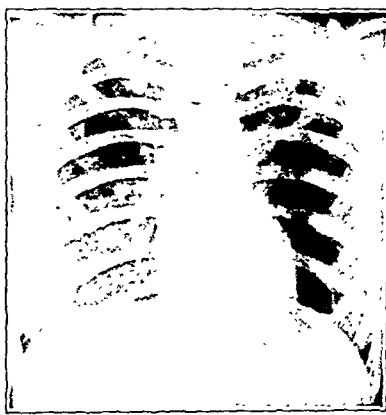

Fig. 11 (case 5).—Appearance in February 1936, when all the classic symptoms of pulmonary tuberculosis developed. Note an exudative bronchopneumonic infiltrate, extending from the left apex to the third interspace and a cavity in the region of the first interspace.

Fig. 12 (case 5).—Present status. Note marked resolution of the bronchopneumonic infiltrate, leaving stringy densities and complete closure of the cavity.

because of the presence of children require immediate hospitalization. If segregation is not immediately available, he should urge the patient suitable for collapse therapy to seek it in properly equipped clinics or from private sources, depending on the economic status of the patient. It has been indicated by the work of the Henry Phipps Institute and in the Chicago Municipal Sanatorium Clinics that collapse therapy in selected cases may be instituted while the patient is at home either awaiting sanatorium admission or refusing to seek admission. Under such conditions many patients become abacillary and their disease is gotten under control so that sanatorium care is subsequently not needed. As a result, many more beds become available for those urgently in need of them. Finally, while the patient is awaiting admission to the sanatorium it should be the physician's duty to instruct him as to precautionary measures.

It is important to take one more factor into consideration, one that is little stressed but nevertheless has a

hazards but also suggest methods of avoiding them. In this respect the general practitioner, and the profession as a whole, should, as it were, "crawl out" of his secluded medical life and exert his influence and prestige to encourage the clearing of slums and the improvement of conditions generally of the people in the lower strata of life.

Thomas Owen.—So let us remember that some one other than a visiting physician or surgeon may indelibly stamp his personality on the hospital he serves. In the old Blockley Hospital in Philadelphia a tablet has been erected to Thomas Owen, who for some thirty years as head nurse of the men's medical floor was known to successive generations of attendants and residents, most of whom are forgotten, or at least their association with that picturesque old hospital has been, while his will remain for all time. And why? Because he gave all that he had to the institution, and it left him famous, whereas the others, a good many of them, used the old Philadelphia Hospital not infrequently for political or private ends and are buried in oblivion.—Cushing, Harvey: Consecratio Medici and Other Papers, Boston, Little, Brown & Co., 1928.

HEMOLYTIC STREPTOCOCCUS
MENINGITISREPORT OF CASE WITH RECOVERY AFTER THE
USE OF PRONTOSIL AND SULFANILAMIDE

EDWARD DYER ANDERSON, M.D.

MINNEAPOLIS

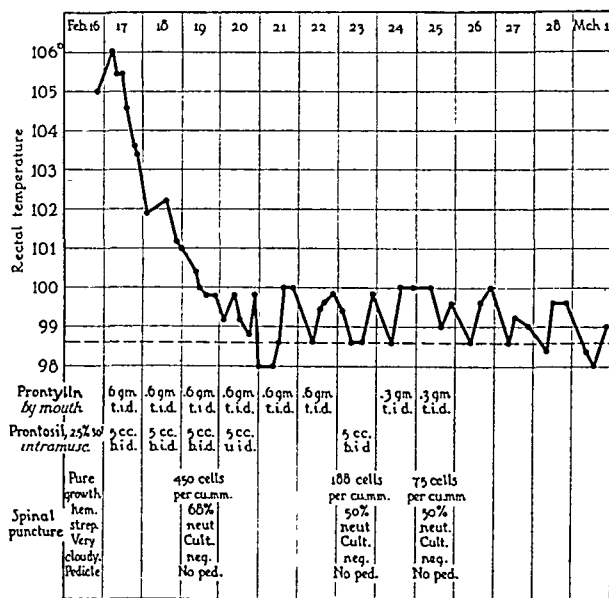

In reviewing the literature one finds reports of cases of recovery in streptococcal meningitis, but these are comparatively rare. In July 1935 Gray¹ presented a summary of the literature on this subject and found sixty-six cases, including his own, reported in the last thirty-five years. He feels that streptococcal meningitis is at least 97 per cent fatal. Since his report there have been nine cases of recovery reported and with the case being reported by me it gives a total of seventy-six cases with recovery reported in the literature in the last thirty-seven years. In seventy-three of the seventy-six cases the treatment consisted of repeated spinal punctures, spinal washings, injections of antistreptococcus serum, blood transfusions or a combination of these methods. In many of these cases the meningitis was of otitic origin, and mastoidectomy was done in many of the cases. In almost all of these seventy-three cases the treatment was carried out over a considerable length of time before the patient was pronounced cured.

There were two cases of particular interest reported in 1936. Walker and King² reported a case in which streptococcal meningitis developed after an induced abortion in which both blood and spinal fluid cultures gave a positive growth of hemolytic streptococci. Transfusions were given daily for ten days with blood taken from donors who had previously had scarlet fever. The patient made an uneventful and fairly rapid recovery. Caussé, Loiseau and Gisselbrecht³ in February 1936 made the first report in the literature of a case of hemolytic streptococcus meningitis with recovery after treatment with prontosil. Their patient was a man, aged 46, in whom a hemolytic streptococcus meningitis of otitic origin developed. After receiving prontosil intravenously and by mouth, he showed definite improvement in twenty-four hours, and in forty-eight hours the spinal fluid was sterile. The patient made a complete recovery.

In February 1935 Domagk⁴ gave an account of chemotherapeutic investigations with mice infected with hemolytic streptococci from human source and treated with various drugs. Among the drugs described was an earlier preparation called prontosil, which was the hydrochloride acid salt of 4-sulfamido-2, 4-diaminoazobenzol, which is a red, crystalline powder. Pharmacologically it is remarkably inert, yet the drug appeared to have a definite elective action on streptococci in mice. He showed this by photomicrographs of smears taken from the peritoneal cavities of infected mice and controls. Encouraging results were also shown in rabbits suffering from chronic streptococcal infections. He showed that it had a definite chemotherapeutic effect on streptococci and to a certain extent on staphylococci. It is practically inert in relation to pneumococci and other pathogenic organisms. Since then his work with

animals has been either partially or completely confirmed by Levaditi and Vaisman,⁵ Hörlein,⁶ Colebrook and Kenny,⁷ Long and Bliss⁸ and Nitti and Bovet.⁹

In the last two years several writers have reported their results with the clinical use of prontosil. Schreus¹⁰ in 1935, Meyer-Heine and Huguenin,¹¹ Kramer¹² and Scheurer¹³ in 1936 reported excellent results when prontosil was used for the treatment of erysipelas. Anselm,¹⁴ Colebrook and Kenny,⁷ and Ley¹⁵ reported most favorably on its use in puerperal fever. Tixier and Eck¹⁶ reported three cases of streptococcal empyema in which excellent recoveries were made after the use of prontosil. As stated previously, Caussé, Loiseau and Gisselbrecht³ reported a case of hemolytic streptococcus meningitis with recovery after the use of prontosil. The consensus of all the authors seems to be that prontosil is of value in the treatment of hemolytic streptococcus infection but apparently has little or no effect on other strains of streptococci or other organ-

Rectal temperature in case of hemolytic streptococcus meningitis.

isms. The drug is apparently nontoxic in ordinary dosage. The way in which it works on hemolytic streptococci is at the present time unknown. Although at first it was thought that the drug should be given intravenously as well as by mouth, it is now generally considered unnecessary to use the intravenous method and it is given intramuscularly and by mouth.

REPORT OF CASE

History.—F. C., a boy, aged 9 years, was brought into Abbott Hospital Tuesday night, Feb. 16, 1937, at 9 p. m. The mother and father were living and well. There were no other children. The boy had always been well until January 1937 except for ordinary infections of the upper respiratory tract. In the early

part of January he had measles. He recovered from this and was apparently well until nine days before admission to the hospital, when pain developed in the left ear, which persisted until two days before admittance to the hospital. The pain was not constant and at no time was it extreme. Although his temperature was not taken, the mother thought it was slightly elevated at times. There was no discharge. Two days before admittance to the hospital he seemed much better and went outdoors the day before. He was seen by a neighbor who was a trained nurse and she thought he looked bad and sent him home after taking his temperature and finding it to be 99.5 by mouth. That evening he complained again of earache on the left side. The next morning, February 16, he woke up complaining of severe headache and had an elevation of temperature. He vomited and as the day went on became very restless. His temperature continued to rise and toward the end of the day he became stuporous with intervals of extreme restlessness. He was sent to the hospital and at the time of entrance his temperature was 105° F. (rectum).

Physical Examination.—He lay in bed in a semistupor and every few minutes would cry out sharply and toss from side to side. He was unable to answer questions. His cheeks were flushed and he had a pained expression.

The physical examination revealed moderate rigidity of the neck with positive Brudzinski's sign, marked hyperesthesia of the entire body and ptosis of the right eyelid. The pupils were dilated and reacted sluggishly to light. Kernig's sign was slightly positive in both legs and the Babinski reflex was negative on both sides. Knee jerks were absent on both sides. The left ear drum appeared dull and was bulging slightly. There was no pulsating of the drum. The right ear drum was normal.

Roentgen examination of both mastoids gave the following picture: The right mastoid was undeveloped. The left mastoid showed a first degree of infiltration of all the cells without evidence of destruction.

The pharynx was slightly reddened. The tonsils were not present. The nose was normal and the heart, lungs and abdomen were normal.

Subsequent Course and Treatment.—A spinal puncture was done and 50 cc. of a markedly cloudy fluid was obtained with slight increase of pressure. A pedicle formed within one hour. A direct smear made from a centrifugated specimen showed no organisms but large numbers of pus cells. Unfortunately, no cell count was made of this specimen. A culture was made on broth and blood agar and twelve hours later the broth showed a pure growth of hemolytic streptococci. Tubes 2 and 3 of this spinal fluid were sent to Dr. W. P. Larson of the University of Minnesota, who obtained from each one a pure culture of hemolytic streptococcus.

Paracentesis of the left ear drum was done and a small amount of serosanguineous discharge was obtained.

The morning of February 17, the boy's temperature was 106° F. by rectum and the general condition was unchanged except that he seemed more stuporous. There was very slight drainage from the ear. He was given 5 cc. of a 2.5 per cent solution of prontosil¹⁷ intramuscularly twice a day and two 0.3 Gm. tablets of sulfanilamide by mouth three times a day. The prontosil was given intramuscularly twice a day until seven doses had been given. Two 0.3 Gm. sulfanilamide tablets were given for six days. Prontosil was then given intramuscularly for one day and then one 0.3 Gm. tablet of sulfanilamide three times a day for two more days, after which all medication was stopped.

His general condition remained the same during the day except that his temperature had dropped to 103.4° F. by rectum by evening. The next morning, February 18, his temperature was 102° F. by rectum, and he seemed markedly improved. He answered questions, recognized his parents and said that he had no pain. He was drowsy all day but could be easily aroused and would answer questions intelligently but sluggishly. There was very slight drainage from the ear.

The next day, February 19, he was much better, took food and fluids well and was much less drowsy. His temperature was 101° in the morning and 99.8° later in the day. Rigidity of the neck was markedly less and ptosis of the eyelid had disappeared. There was no hyperesthesia. The ear was dry. A spinal puncture was done and 20 cc. of fluid was obtained

with slight increase of pressure. The fluid appeared much less cloudy than the original specimen. There were 450 cells per cubic millimeter, showing 68 per cent polymorphonuclears. A culture taken from this specimen was negative. The following day, February 20, he was still slightly drowsy but at times wanted to sit up, wished to look at funny pictures and in every way was markedly improved. Rigidity of the neck was gone.

The boy continued to improve and by February 22 seemed perfectly normal. He had no complaints, ate well, played the radio, read when allowed to and said he had no pain or discomfort. Spinal puncture made February 23, one week after admission, gave a nearly clear fluid under pressure; the cell count was 188, with 50 per cent polymorphonuclears, and culture was negative.

February 25, 15 cc. of clear fluid under practically normal pressure was obtained on spinal puncture and there were 75 cells per cubic millimeter with 50 per cent polymorphonuclears. Culture was negative.¹⁸

SUMMARY

In a case of hemolytic streptococcal meningitis there was rapid, complete recovery following the use of prontosil and sulfanilamide.

301 Kenwood Parkway.

THE DIAGNOSIS OF ADDISON'S DISEASE

EDWARD M. KLINE, M.D.

Instructor, Department of Internal Medicine, University of Michigan Medical School

ANN ARBOR, MICH.

Although the typical case of Addison's disease can be recognized clinically, the laboratory becomes an indispensable aid in the diagnosis of those cases which do not entirely fit the ordinary picture. Realizing the serious prognosis implied in such a diagnosis, as well as the importance of evaluating the therapy, my associates and I have in doubtful cases employed the salt restriction test suggested by Harrop and his co-workers¹ for final diagnosis.

In cases of Addison's disease during restriction of sodium chloride, signs of early relapse can be expected any time after the first day but usually somewhere between the third and the fifth. Characteristic concomitant alterations in the blood are lowering of the sodium and chloride, elevation of potassium and nitrogen, hemoconcentration and diminution in blood volume. An example of this is the case of T. M., in whom a typical addisonian crisis occurred on the fifth day following a change in his diet from one containing approximately 12 Gm. of sodium chloride daily to one containing only from 1 to 4 Gm. daily. Associated with this there was an increase in the blood nonprotein nitrogen from 35.2 mg. to 48 mg. per hundred cubic centimeters, an increase in the hematocrit from 45 per cent (per cent of cells) to 49 per cent, a fall in plasma chloride from 326 mg. to 284 mg. per hundred cubic centimeters and the extremely low plasma sodium of 223 mg. per hundred cubic centimeters. Prompt recovery followed the intravenous administration of 3,000 cc. of physiologic solution of sodium chloride. No extract was used.

18. The boy left the hospital ten days later apparently perfectly well and when seen by me three weeks later was in excellent physical condition and showed no evidence of sequelae.

Mrs. Genevieve Bourke prepared the diets used.

From the Department of Internal Medicine, University of Michigan Medical School.

1. Harrop, G. A.; Weinstein, Albert; Soffer, L. J., and Treacher, J. H.: The Diagnosis and Treatment of Addison's Disease, J. A. M. A. 100: 1850-1855 (June 10) 1933.

17. The prontosil used was manufactured by the Winthrop Chemical Company. This is the diodium salt of 4-sulfamidophenyl-2-azo-7-acetyl-5-methyl-3-hydroxyphenylalanine-3, 6-disulfonic acid.

To depend on the presence or absence of subjective improvement following the administration of adrenal cortex extract for diagnostic information is subject to criticism. That no such marked specificity of treatment is to be expected is shown by the existence of doubt in the minds of many,² in regard to its actual usefulness in the treatment of proved cases. It is my impression that the latter method is employed frequently when laboratory facilities are wanting and in some cases has led to incorrect diagnosis and the fostering of an expensive and unnecessary type of therapy. This is well exemplified in the following protocol:

History.—H. M., a salesman, aged 48, was admitted to the hospital Dec. 14, 1935. Although his general health had been good, within the past three years there had been a gradual onset of weakness, loss of libido, and a darkening of the skin. Three months previous to admission a presumptive diagnosis of Addison's disease had been made, and the administration of a commercial adrenal extract was attended by such improvement that a daily injection had been continued until the time of his admission here.

Speaking of this placebo in a letter dated April 9, 1936, the patient states, "It is truly amazing how I picked up after taking those shots. My color was better than in a long, long time and my stomach and general condition was much improved."

COMMENT

This demonstrates well the psychic stimulation attending the administration of an injectible substance which, to this neurasthenic patient, was quite indistinguishable from potent adrenal cortex extract. Hartman³ suggests the use of adrenal cortex extract in all asthenic states "which cannot be accounted for by known cause," not as a diagnostic test but as a therapeutic measure. It occurs to me that these patients might be, to a large extent, of the psychoneurotic group receiving their benefit in a nonspecific way from the actual injection itself. Since patients of this type are apt to exhibit favorable response to suggestive therapy, one must be on guard not to mistake this for genuine improvement in an organic disease. It is my opinion that if adrenal cortex extract is to be used the dose should be large and

* This is computed from standard food tables. All other figures represent actual determinations.

Examination.—The blood pressure was 110 systolic, 70 diastolic. Although there was a uniform tanning of the skin, this was not present on the mucous membranes and was not darker than that seen in many brunette individuals.

Special Studies.—The examinations of the urine and blood were negative. The Kahn test was negative. The basal metabolic rate December 17 was —19 per cent. The dextrose tolerance test (with 1.75 Gm. of dextrose per kilogram of ideal weight) was: fasting 78 mg. per hundred cubic centimeters, first hour 113, second hour 101 and third hour 40. Stereoscopic roentgenograms of the chest were negative for tuberculosis. Films of the adrenal areas demonstrated no calcification.

Hospital Course.—To clarify the diagnosis the patient was placed on a low sodium chloride diet (from 1 to 1.7 Gm. daily) and although he complained of nausea and weakness on occasion there were none of the usual changes of the blood seen in cases of Addison's disease (as shown in the table). Desiccated thyroid gland given over the next two months in amounts that maintained the basal metabolism at a normal rate (+4 per cent Jan. 24, 1936) did not relieve his symptoms.

So fixed was the belief in the patient's mind that he would be quite well after a course of parenteral adrenal cortex extract that it was suggested by others of the staff (Drs. A. C. Curtis and Robert S. Ballmer) that a placebo be tried in preference. Thus he received between Feb. 6, and Feb. 14, 1936, four subcutaneous injections of sterile distilled water, and so marked was the improvement that he was discharged on February 20.

the treatments frequent but it should be reserved for the case of outspoken Addison's disease.

Recently Wilder and his co-workers⁴ at the Mayo Clinic have shown that in cases of Addison's disease an increase in the intake of potassium may augment the urinary loss of sodium and provoke a crisis even when the sodium chloride intake is high (18 Gm.). Likewise a lower sodium chloride intake may be tolerated in the presence of a restriction of potassium. Therefore, as they have pointed out, it would seem desirable in the future when using the salt restriction test to keep the potassium intake high (4 Gm. or more).

It should be emphasized that the low salt diet is not without danger to the patient with Addison's disease, especially when allowed to progress to the point of crisis. Although it has been clearly shown that the extract has no value when used alone in the treatment of acute relapse,⁵ Harrop¹ feels that it may be a life-saving measure when used in large amounts in conjunction with intravenous sodium chloride. It should always be on hand to be used in case of an emergency.

THE OCCURRENCE OF DIPLOCOCCUS PNEUMONIAE IN INFECTIONS OF THE URINARY TRACT

H. D. MOOR, M.D.

AND

IDA LUCILLE BROWN, M.T., M.S.

OKLAHOMA CITY

In October 1929 Dr. Robert H. Akin of the Department of Urology of the University of Oklahoma School of Medicine brought to us a smear of prostatic secretion stained with methylene blue. The patient from whom the slide was taken called on the doctor complaining of burning on urination and a urethral discharge, although at the time no discharge was evident. There was no history of *Neisseria gonorrhoeae* infection for the previous three months. Microscopic examination of the stained slide showed numerous clumped pus cells and a lancet shaped diplococcus with a suggestion of a capsule. Attempts to cultivate this organism at that time were unsuccessful. During the following six years we noticed the same organism in various urethral and prostatic smears and in urinary specimens brought to us for examination.

July 1, 1935, funds were made available by legislative appropriation to permit the Department of Bacteriology to carry on a careful bacteriologic and clinical investigation of this problem. Dr. Akin investigated the clinical aspects of these infections and will make a separate report. Our report deals primarily with the bacteriologic aspects of the problem. Dr. Akin secured the specimens from his patients for our work. This problem was considered to be of special importance, as many of the patients had been previously diagnosed as having gonorrhea. Hence the social aspects of the infection had to be considered. Owing to the fact that the organism when seen in direct smear and stained with gram stain was a gram-positive lancet shaped diplococcus associated with pus, we thought that it might be a pneumococcus and carried on our investigations accordingly.

A considerable amount of work has been done relative to pneumococcal infections and their effect on the organs of the genito-urinary tract, especially the kidney. The work of Blackman¹ and of Blackman and Rake² is outstanding. Their work deals with the effect on the kidney of the toxic products produced by pneumococci. They did not make a bacteriologic study of the urine. Barney³ reported 121 cases of pyogenic coccus infections of the kidney but did not identify them bacteriologically and made no specific reference to pneumococci. Cabot and Nesbitt⁴ reported a study of twenty-seven cases of coccic infections of the urinary tract and their relation to the upper respiratory tract. They made their diagnosis by direct smears and did not attempt to culture the micro-organism. Bolend⁵ in 1924 reported an organism resembling in some respects *Diplococcus*

pneumoniae from genito-urinary tract infections, similar to the organism with which we are working, which he called a pseudogonococcus. He pointed out that this organism did not correspond with any known diplococcus described at that time. He studied this organism morphologically, culturally, serologically and by animal inoculation.

Gibson and Wiley⁶ reported that gram-positive diplococci morphologically resembling pneumococci are very commonly found in genito-urinary infections but did not identify them culturally or serologically. Neale⁷ reported a study of kidney complications in lobar pneumonia but carried out no cultural investigations. Matzenauer⁸ reported a case of inflammation of the urethra due to pneumococci. The patient gave a doubtful history of no contact with the organism. It was of metastatic origin from antedating grippal infection of the upper respiratory tract. Stadnichenko⁹ reported thirty strains of gram-positive cocci isolated from kidney infections, all of which were staphylococci. Sujoy¹⁰ reported a case of urethrocystopyelitis in a child who developed pneumococcal vaginitis. Treatment of this case with ethylhydrocupreine gave satisfactory results.

Bergey¹¹ lists only one gram-positive diplococcus other than the pneumococci, i. e., *Diplococcus pluton*, which is accused of causing foulbrood in bees; but this organism does not grow on artificial mediums. Zinsser and Bayne-Jones¹² do not mention pneumococci as a cause of genito-urinary infection. This is true as far as we know of all other textbooks of bacteriology.

The literature reviewed to date concerning genito-urinary tract infections by pyogenic cocci reveals no extensive investigation that deals with the existence of pneumococci as the causative agent in these infections.

Up to the present time we have examined and cultured specimens from 384 patients, 329 of whom were suffering from genito-urinary symptoms. The remainder were apparently healthy medical students who gave no history of genito-urinary trouble except one who had had renal colic. At least two specimens were cultured from each patient and in many cases as many as six. All specimens from female patients were obtained by catheterization. Those from male patients were obtained by first cleansing the external genitals with soap and water and then applying 70 per cent alcohol with sterile cotton applicators or 4 per cent mercurochrome. Excess alcohol or mercurochrome was removed with sterile gauze. The first urine voided was discarded, the second and third specimens were saved. These specimens will be referred to in this paper as second and third urines. Many specimens were obtained after prostatic massage.

All specimens were preliminarily cultured by adding approximately 1 cc. of urine to 7 cc. of brain heart infusion broth. If no growth was obtained after nine days' incubation, the culture was discarded and recorded as sterile. We usually had growth in from twenty-four

to forty-eight hours. When growth was obtained the culture was examined morphologically by the gram staining technic. In three cases a gram-positive diplococcus appeared in the culture after three days' incubation. If organisms other than gram-positive diplococci or streptococci were obtained, such as staphylococci, gram-positive or gram-negative bacilli and Sarcina, these morphologic types were recorded but the cultures were discarded. All cultures showing gram-positive diplococci or streptococci were saved for further identification. If a mixed culture was obtained showing either of the foregoing two organisms, it was streaked on brain heart infusion plates and typical colonies were picked and saved for identification. Mixed cultures were obtained in only five cases, the remainder of our diplococci or streptococci being pure cultures on primary isolation. The distribution of types of organisms and sterile cultures from patients showing genito-urinary symptoms was as follows:

Gram-positive lancet shaped diplococci (some appearing as diplostreptococci), 96.

Streptococci (not showing diplo formation in the chains), 2.

Staphylococci in second urine, third urine being sterile from same patients, 44.

Staphylococci in second and third urines, 47.

Gram-negative rods, 15.

Gram-positive spore bearing rods, 19.

Sarcina, 6.

Sterile second and third urines for nine days or longer, 98.

Small yeasts (not identified), 2.

Total 329.

Specimens from healthy controls cultured in the same manner showed the following results:

Sterile, 29.

Streptococci, 5.

Staphylococci, 11.

Sarcina, 2.

Gram-negative bacilli, 3.

Mixed staphylococci and streptococci, 5.

Total, 55. None of the healthy controls showed gram-positive diplococci.

Cultures saved for identification were transferred to the following mediums: gelatin, litmus milk; plain nutrient agar, Russell's double sugar agar, brain heart infusion agar slants and plates, dextrose agar, blood agar; plain nutrient, saccharose, lactose, dextrose, adonite, arabinose, dextrin, salicin, raffinose, dulcitol, xylose, galactose, mannose, mannitol, inulin and maltose broths; and Hiss inulin serum water. All carbohydrate broths were made by adding 1 per cent of the sugar to a base of brain heart infusion broth. Phenol red was used as an indicator and all mediums were adjusted to a pH of 7.4. Bile solubility tests were run on the preliminary twenty-four hour brain heart infusion broth cultures.

All the diplococci gave the cultural characteristics of pneumococci. All sugars, including inulin, were fermented with the production of acid but no gas. There was no liquefaction of gelatin. Litmus milk became acid with coagulation on the fourth or fifth day. There was no gas in dextrose agar, and Russell's double sugar gave an acid slope, alkaline butt and no gas. On blood agar, colonies appeared small, discrete and glistening with a slight area of green around each colony. There was a very scanty growth or none at all on plain nutrient agar or broth. All ninety-six cultures were bile soluble.

Twenty-seven cultures, morphologically and culturally identical to and typical of pneumococci, were injected into the peritoneal cavity of white mice. The cultures were all moderately virulent for mice, two of

them died in two days, the other twenty-five became sick showing toxic effects. The same organisms were recovered from the peritoneal exudate. These organisms in direct smear had shown a faint capsule, which was lost on repeated cultivation and was not regained by mouse passage. Agglutination tests were run, each of the twenty-seven cultures being used as an antigen against each of the thirty-two types of antipneumococcus serum. All cultures agglutinated with type XIV antiserum. No cross agglutination with any other type was noted. Cooper, and others¹³ in a study of the twenty-nine types usually spoken of as type IV group found that type XIV was one of the most prevalent types found in the pneumonias of children and that this type was moderately virulent for mice. This corresponds with our observations in regard to pathogenicity of type XIV for mice.

After finding that these cultures were type XIV, we next tested the agglutinating power of the serum of a patient who had repeatedly given positive urine cultures for diplococci and who had had a urinary tract involvement for some time but whose blood cultures were negative. Twelve pure cultures, including one isolated from the patient himself, were used against this serum. Positive agglutination with undiluted serum, serum diluted 1:10 and 1:20 was obtained with each culture except one, which agglutinated only with undiluted serum. As a control we used the serum of an individual who gave no history of pneumonia or pneumococcal infection of any kind against the same twelve cultures. No agglutination with undiluted serum was obtained with ten of the cultures; the other two showed only a slight agglutination after an hour's incubation.

In three of the ninety-six cases in which we demonstrated typical diplococci in the urine, we were able to recover the same organism from the blood. Dr. William H. Bailey of the clinical staff and pathologist of Wesley Hospital, Oklahoma City, furnished us with a culture obtained from the blood of a patient suffering from a paranephric abscess. This culture proved to be a typical diplococcus identical with the others with which we were working. He also sent us a culture from the urine of the same patient, which contained the same organism. At operation the same organism was recovered from the pus in the abscess. In four cases, one of which gave a positive blood culture, we found the organism in infected teeth. After the offending teeth were removed we were no longer able to isolate the organisms from the urine, and symptoms disappeared.

Autogenous vaccines were prepared from the cultures obtained from each of the ninety-six positive cases. These vaccines were administered by Dr. Akin with very favorable results to date. In nineteen cases in which the vaccine has been administered three months or longer we can no longer recover diplococci from the urine, and Dr. Akin reports that symptoms have disappeared in these cases. Many of these infections, which have now cleared up, have been of long standing chronic character, one patient giving a history of having had the infection fifteen years. This phase of the work is still in progress.

SUMMARY

Cultures of urine from 329 persons suffering from genito-urinary tract infections have been positive in ninety-six cases (approximately 30 per cent) for a

Exper. Med.* 49:461 (March) 1929. Cooper, Georgia; Rosenstein, Carolyn; Walter, Annabel, and Peizer, Lenore, *ibid.* 55:531 (April) 1932.

gram-positive lancet shaped diplococcus which by culture and serologic tests proved to be *Diplococcus pneumoniae*. In twenty-seven of the cases we have typed the organism and found it to be type XIV. The remaining sixty-nine cultures, while not typed, are definitely pneumococci, being bile soluble and fermenting inulin as well as giving the other typical cultural characteristics. Fifty-five controls proved negative for pneumococci.

Autogenous vaccines have given encouraging results to date. Nine of the cases with which we worked gave positive cultures of the diplococcus from sources other than the urine; four from the blood and the urine and four from the teeth and the urine; one from paraneurphic abscess, blood and urine.

CONCLUSION

Thus far we have been able to demonstrate only type XIV pneumococcus, but it is highly probable that other types may be involved.

Infections of the urinary tract due to pneumococcus occur and are relatively common.

801 East Thirteenth Street.

PNEUMATURIA IN DIABETES MELLITUS

REPORT OF A CASE

FRANCIS G. RILEY, M.D.

AND

FLOYD H. BRAGDON, M.D.

JAMAICA, NEW YORK

Pneumaturia may be defined¹ as the passage of urine charged with air or gas. Senator² in 1891 offered the first classification of pneumaturia, dividing it into three classes: (1) atmospheric air entering the urinary bladder as in instrumentation; (2) gases entering from hollow body cavities, especially from the intestine; (3) decomposition or fermentation of the urine causing gasification in the urinary bladder. The third group may be further divided into those with glycosuria and those without glycosuria. We are primarily interested in this communication with class 3, reporting a case of pneumaturia associated with diabetes.

HISTORICAL

Kelly and MacCallum³ in 1898 reviewed the literature and reported several cases of pneumaturia, none of which were associated with diabetes. A careful search of subsequent literature has failed to reveal a report on this subject in the American or English literature, although several German observers have reported cases. Briene de Boismont⁴ first mentioned spontaneous production of gas in the bladder in 1825 and considered it a secretion by the mucosa. Roache confirmed this and Chomel added the suggestion that the gas might be due to fermentation. Practically all cases reported up to 1860 were fistulous in character, but in that year Raciborski⁵ had a case not due to fistula and reported it as a spontaneous development in the bladder. He named it pneumo-uria. Keyes⁶ reported two cases of

pneumo-uria in 1882 in two men, aged 67 and 68 respectively, with hypertrophy of the prostate in which there had been instrumentation. Guiard⁷ first pointed out pneumaturia in diabetes in 1883 and reported four cases. Duménil⁸ and Thomas⁹ each reported a similar case. Müller¹⁰ in reporting pneumaturia in diabetes in 1888 gave the first analysis of the gas found, showing predominantly carbon dioxide, hydrogen and nitrogen. When gas was present the urine was acid, but ammoniacal decomposition interrupted and arrested the gasification. On standing, the sugar disappeared from the urine. Senator² reported a similar case associated with cystitis, the urine having the odor of a fermented yeast mixture. The reaction was always acid. The gas was largely carbon dioxide, and the fermented urine contained considerable alcohol on distillation. Yeast cells were found in the urine. Teschenmacher¹¹ reported three cases. Favre¹² in 1888 isolated a gas-forming bacterium at autopsy from the urine of a nondiabetic woman with cystitis and pyelonephritis. There was gas inflation of the bladder and ureters. This was the first attempt to demonstrate a causative agent. French authors subsequently reported the colon group and occasionally *Bacillus lactis-aerogenes* as causative agents, especially in the nondiabetic group. Luetscher¹³ was of the opinion that *B. lactis-aerogenes* was a rare cause of cystitis. Ernst¹⁴ in 1894 reported a case of diabetes presenting a yeast infection of the bladder. Fisch¹⁵ in 1898 reported pneumaturia in diabetes associated with yeast infection and cystitis. Müllern-Aspegren¹⁶ reported a case in 1921 of diabetes presenting prostatic hypertrophy associated with yeast infection and pneumaturia in a man, aged 73. He was cured on bladder irrigations. Two years later Tannenberg¹⁷ reported a case of diabetes presenting bilateral renal and vesical thrush infection but did not mention pneumaturia. Ota and Masuda¹⁸ stated that yeast infection of the bladder is not unusual in diabetic patients but is uncommon in those without glycosuria. They report a case in the latter category. Sharkey and Root¹⁹ reviewed 196 cases of infection of the urinary tract in diabetic patients coming to autopsy, reporting one case of bladder paralysis, but they do not mention pneumaturia or yeast infection.

Cystitis emphysematosa has been mentioned from time to time in association with diabetes. It does not concern us in this communication except to differentiate it from true pneumaturia. Cystitis emphysematosa is characterized by the presence of gas-containing vesicles and cysts in the wall of the urinary bladder. Sanes and Doroshow²⁰ report finding *B. coli* in the urine of a woman with diabetes.

PREDISPOSING FACTORS

Summation of the cases of pneumaturia reveal fourteen cases associated with glycosuria. There was a history of instrumentation preceding the appearance of the gas in practically all cases and a marked increase in the quantity of the gas in the remainder. It is now agreed that instrumentation is an essential factor in the production of pneumaturia of this type. The urine was acid in the majority of cases preceding instrumentation. Later the reaction varied according to the nature of the organism introduced. The organism was not identified in the earlier cases, but in the later reports *B. coli*, *B. lactis-aerogenes* and yeast were the most frequent. The presence of residual urine offers a favorable medium for the growth of organisms. Other predisposing factors are vesical calculi and general debility with lowered body resistance. The susceptibility of the diabetic patient to infection is well known. The sugar present in the urine favors bacterial and saccharomycelial growth. This is evidenced by the more frequent occurrence of pneumaturia with glycosuria than with sugar-free urine.

On analysis the gas (Senator) was found to be carbon dioxide 9 per cent, hydrogen 57 per cent and nitrogen 35 per cent. When the gas was allowed to stand twenty-four hours the carbon dioxide content increased to 20 per cent and the hydrogen decreased to 44 per cent. The gas was odorless and clear. The urine was always acid when gas was present and neutral or alkaline when ammoniacal decomposition set in. The gas was due to fermentation with the production of butyric and lactic acids. Distillation of the urine yielded considerable alcohol.

SYMPTOMS

The symptoms are not striking. There may be a continuous desire to urinate as a result of the cystitis. The passage of air causes no pain but a tickling sensation and may be accompanied by a soufflé or explosive report. The gas does not pass until most of the urine is expelled, owing to the curve of the urethra. The urine may be cloudy and usually contains pus.

Recovery is rapid in many cases with lavage of the bladder. Death is due to infection of other organs such as pyelonephritis with uremia.

The fifteenth case, reported at this time, was observed at the Queens General Hospital:

REPORT OF CASE

History.—A white man, aged 52, admitted Dec. 28, 1935, to the medical service, complained of painful swelling of the left great toe. The family history was not contributory. The past history revealed a fall thirteen years previously in which the left testicle was injured, with residual swelling. He was treated in a Brooklyn Hospital three years before the present admission for diabetes, remaining in the institution two months. No treatment or diet had been followed since his discharge. Three days before admission the patient sustained an injury to the left great toe, which was followed by painful swelling and suppuration. No symptoms of diabetes were elicited at the time of admission. He complained of passing small amounts of urine but no pain. Nocturia amounted to four times during the night.

Examination.—On physical examination the patient was somewhat asthenic but not acutely ill. There was slight dependent edema but no dyspnea or cyanosis. The head and neck were normal. The lungs were clear. There was a systolic murmur at the apex of the heart. Blood pressure was 168 systolic; 100 diastolic. The bladder presented as a tumor mass extending from 2 to 3 cm. above the umbilicus; it was not tender and showed no tympany at this time. On rectal examination the prostate gland was not enlarged. Neurologic examination revealed superficial reflexes present and equal; deep reflexes were absent.

On admission, examination of the urine revealed: specific gravity 1.024, acid, sugar 4 plus, acetone none. Tests for butyric and lactic acids and alcohol were not performed. Microscopic examination revealed many white blood cells and red blood cells. Hemoglobin was 90 per cent, polymorphonuclears 67 per cent, lymphocytes 23 per cent. Blood and spinal fluid Wassermann tests were negative. The colloidal gold test was negative. Spinal puncture showed normal pressure, appearance and cell count. Roentgenograms of the chest showed a small pleural effusion at the left base. Roentgenograms of the pelvis were negative. A urine concentration-dilution test showed a variation of specific gravity from 1.012 to 1.017. Blood chemistry showed: sugar 363 mg. per hundred cubic centimeters of blood, urea nitrogen 15.1 mg., nonprotein nitrogen 39.1 mg.

Course.—The patient was placed on a diet of protein 60 Gm., fat 50 Gm., carbohydrate 200 Gm. with insulin 15-10-15 units. The patient voided small amounts but was catheterized daily. The course was afebrile until the twelfth day after admission, when the temperature rose to 101 F. and the following day to 103.8 F. There was a daily elevation to about 100 F., occasionally 101 F. the remainder of his illness. The urine was free of sugar during this time (shown in the table) and the patient was frequently in insulin shock, the blood sugar and carbon dioxide combining power of serum being the only guides

Subsequent Blood Chemistry

1/7/36	Blood sugar	318 mg. per 100 cc.; urine sugar, 0; acetone, 0
1/14/36	Blood sugar	466 mg. per 100 cc.; urine sugar, 2+, acetone, 0
1/18/36	Blood sugar	263 mg. per 100 cc.; urine sugar, 0; acetone, 0
	Urea	45.4 mg. per 100 cc.
	Creatinine	1.4 mg. per 100 cc.
	Nonprotein nitrogen	68 mg. per 100 cc.
	Carbon dioxide combining power	38.6 volumes per cent
1/20/36	Sugar	443 mg. per 100 cc.; urine sugar, 0
	Urea	38.2 mg. per 100 cc.
	Nonprotein nitrogen	71 mg. per 100 cc.
1/25/36	Sugar	91 mg. per 100 cc.; urine sugar, 2+
2/1/36	Sugar	224 mg. per 100 cc.
	Urea	122 mg. per 100 cc.
	Nonprotein nitrogen	170 mg. per 100 cc.

in the treatment. Blood pressure at this time was 125 systolic, 85 diastolic. The patient was seen several times by the genito-urinary service but owing to his condition cystoscopy was not done until twenty-eight days after admission. At cystoscopy the urine was milky in appearance and had a yeastlike odor. Microscopic examination at once revealed the presence of yeast bodies and innumerable white blood cells. The bladder was large and trabeculated, but sensation was normal throughout. There was a generalized inflammatory reaction of the mucosa. Indigo carmine (0.4 Gm.) injected intravenously failed to appear at either ureteral orifice in twenty minutes. Catheters met obstruction bilaterally at from 3 to 4 cm. and could not be passed farther. Cultures of the urine yielded yeast and *B. coli*. Roentgenograms several days later revealed an air bubble in the bladder and catheterization was productive of air bubbles, particularly terminally, and the urine still had the odor of yeast. The patient could void on standing up but not on lying down. He was transferred to the genito-urinary service at this time and bladder irrigation with sodium bicarbonate solution was instituted. Alkalis were given by mouth. This resulted in clearing up the urine, but the patient became comatose three days later and went rapidly down hill. He died in uremia Feb. 4, 1936, thirty-nine days after admission. Diagnosis at death was diabetes mellitus, pyelonephritis with uremia, acute cystitis and the presence of air in the bladder due to yeast infection.

Autopsy.—This was performed by Dr. Santora of the pathology department.

The body measured 5 feet 4 inches (162.5 cm.) and weighed 94 pounds (42.6 Kg.) and was markedly emaciated. The musculature was poorly developed. There was no fluid in the

serous cavities. The heart weighed 330 Gm. and the left ventricle was the site of an old infarct 2 cm. across with fibrosis and a mural thrombus. The myocardium was generally reddish brown. The left anterior descending coronary artery was completely occluded 2 cm. from its origin. The lungs weighed 550 and 660 Gm. respectively. There was a small patch of pneumonic consolidation in the left lower lobe. The right lung showed an area of caseation and cavitation with marked fibrotic changes. The liver, weighing 1,630 Gm., was not remarkable except for mild fatty infiltration. The right kidney weighed 280 Gm. The capsule stripped with ease, showing numerous cortical abscesses and an old healed infarct. Section revealed the cortex and medulla swollen, and numerous irregular well demarcated yellowish patches surrounding the pyramids. The areas were firm without softening. The pelvis was dilated and there were small ulcerations. The ureters were dilated and there were several strictures at the entrance of the ureters into the bladder. The bladder was collapsed, containing a small amount of milky white urine. The mucosa was injected and ulcerated. The prostate was slightly enlarged. The spleen weighed 250 Gm. and was congested. The pancreas weighed 50 Gm. and was markedly flattened and infiltrated with fatty tissue, there being little pancreatic tissue visible in the gross. The adrenal glands were not remarkable. The aorta showed moderate atherosclerosis.

Bacteriology.—Culture on Sabouraud's medium showed non-pathogenic yeast. Intravenous inoculation of the culture into rabbits produced no lesions in one and three weeks, respectively, on postmortem examination.

Microscopic Examination.—Sections of the lung showed a large abscess containing numerous polymorphonuclears and several large areas of caseation. Numerous small tubercles were noted. There were also areas of pneumonic consolidation. Section through the old infarct of the heart showed hyalinization and fibrosis. The muscle fibers were not remarkable. There were areas of focal necrosis in the liver, with granulation and vacuolization of the cytoplasm; the cells were swollen, occluding the sinusoids. The pancreas showed mainly fat tissue with little pancreatic tissue and included islet tissue. The aorta showed intimal thickening, with no destruction of the media.

The kidney showed large abscess areas with central necrosis but not complete dissolution of the tissue. There were many bacteria in the central portion. An area of polynuclear cell infiltration surrounded these areas. These abscesses were at the head of the papilla for the most part, and the intervening tissue was normal. Smears taken from the center of these areas at the time of autopsy and stained with the Gram stain, showed large, fat gram-positive bacilli and did not resemble *B. welchii* but were not cultured, and smaller gram-negative bacilli resembled morphologically the colon group.

The bladder showed thickening of the wall with occasional areas of lymphocytic infiltration of the submucosa and ulceration of the mucous membrane. The inflammatory reaction was not extensive in the section. There was some engorgement of the vessels.

The anatomic diagnosis was (1) acute suppurative cystitis, bilateral hydro-ureter; (2) acute suppurative pyelonephritis; (3) atrophy and fatty infiltration of the pancreas; (4) limited pulmonary bronchopneumonia; (5) pulmonary tuberculosis, limited and fibrotic; (6) coronary sclerosis with old occlusion and old myocardial infarct with mural aneurysm and mural thrombosis, (7) acute parenchymatous degeneration of the liver.

COMMENT

This case presents several interesting phenomena. The picture on admission was typical of diabetes with high blood sugar and glycosuria four plus. Because of the urinary retention, daily catheterization was performed, resulting in cystitis with disappearance of the sugar from the urine. Control of the diabetes was difficult, with alternating periods of insulin shock and hyperglycemia. The absence of sugar in the urine in the presence of an elevated blood sugar was due to fermentation of the urinary sugar with the production of butyric acid, lactic acid and carbon dioxide. This process made the urine consistently acid, further promoting yeast growth. Yeast organisms, apparently non-

pathogenic, were introduced into the bladder with catheterization, and the urinary sugar afforded an excellent culture medium. The production of carbon dioxide and hydrogen resulted in pneumaturia. Owing to the curve of the urethra, the gas was expelled toward the end of micturition. The patient was unable to void when reclining but could do so when erect. This may be explained on the basis of the air bubble forming at the vesical neck when the patient was lying down, inhibiting the action of the sphincter. The gas formed at the fundus of the bladder when the patient was erect. Roentgenograms confirmed the presence of air in the bladder, which is sometimes mistaken for gas in the bowel.

PATHOLOGY

The bladder showed a moderate generalized inflammatory reaction with injection of the vessels. The ulcerations of the mucosa observed at autopsy were probably terminal, as they were not observed at the time of cystoscopy eleven days before death. Non-pathogenic yeast infection produces little inflammatory reaction in itself but is frequently associated with pyogenic invasion. Pathogenic varieties, as *Oidium albicans*, result in the typical lesions. The strictures of the ureters are probably of long duration and not related to the present illness. They were undoubtedly contributory to the terminal pyelonephritis through mechanical obstruction. *B. coli* was cultured from the urine along with the yeast. Organisms morphologically resembling *B. coli* were observed on smears from the kidney abscesses, suggesting this organism as the pyogenic invader. The microscopic picture of the kidney lesions suggested recent origin, as there was incomplete dissolution of tissue in the central part of the abscesses. The firmness of the lesions in the gross supports this view.

The injection of the yeast culture intravenously into rabbits is a questionable test of virulence. No lesions were produced, nor was the health of the rabbits apparently affected. Mouse inoculation was unfortunately not done.

TREATMENT

Treatment consists in bladder lavage and is usually efficacious in clearing up the infection. The nature of the infection would determine the irrigating solution. In the colon group, acriflavine solution 1:5,000 or an acid reagent such as boric acid 4 per cent, or phosphoric acid 1 per cent has proved most useful. Yeast is cultured in an acid medium, indicating that an alkaline solution such as sodium bicarbonate would be of value. The ingestion of alkaline or acid substances and regulation of the diet further influence the urinary reaction.

PROGNOSIS

The uncomplicated cases clear up rapidly on irrigation. The pneumaturia disappears and sugar reappears in the urine. Needless to say, control of the diabetes aids in treatment. The presence of the infection, however, renders control of the diabetes difficult. Death is usually due to extension of the infection or to secondary invasion, such as pyelonephritis. This was true in the case reported. The urine cleared up at once with continuous bladder irrigation, but there was extensive pyogenic kidney involvement.

It is likely that the incidence of pneumaturia is greater than the number of cases reported would indicate. This may be due to the malady not being recognized or to failure to report the cases. In a perusal of the literature on diabetes, cases suggesting pneu-

maturia are noted from time to time. Jordan and Crabtree²¹ reported seven cases of bladder paralysis associated with diabetes, apparently neurogenic in character. Six of the cases presented paresthesias and neurologic signs, but the seventh was essentially negative neurologically. Roentgenograms of the abdomen in this case revealed gas in the bladder. It is possible that this may have been a case of pneumaturia associated with diabetes.

SUMMARY

Pneumaturia in a diabetic patient was due to a non-pathogenic yeast infection of the bladder. Fourteen cases of pneumaturia associated with diabetes mellitus were found in a review of the literature. It is thought that the incidence is greater than the number of cases reported would indicate and that many cases go unrecognized. Yeast is the most common organism concerned in the cystitis. Instrumentation usually precedes the infection. The diagnosis depends on the presence of gas bubbles in the urine and may be confirmed roentgenologically. Treatment by bladder lavage is usually curative. Death is due to concomitant infection, usually pyelonephritis.

HEREDITARY FACTORS IN EPILEPSY

DIFFERENCES BETWEEN DETERIORATED AND NONDETERIORATED PATIENTS

HARRY A. PASKIND, M.D.
AND
MEYER BROWN, M.D.
CHICAGO

In attempts to unearth the etiologic basis of epilepsy no subject has been more thoroughly scrutinized than the rôle of heredity, and it may appear late in the day to add another contribution on this subject. Our reason for so doing is that a review of the literature has convinced us that such studies have only partial value because they have been based in almost all instances on institutional, deteriorated patients. Writers on the heredity of epilepsy have been mainly workers in hospitals and colonies, who had access only to epileptic patients sent there on account of deterioration or other psychosis, and there are good reasons for believing that these constitute a minority, perhaps a small minority, of persons with epilepsy. Since the studies of most writers were circumscribed by institution walls, the vast number of nondeteriorated persons with epilepsy who successfully adjust in the outside world have escaped observation and hence have been excluded from studies estimating the hereditary factors in epilepsy. In addition, the conclusions of some writers have been further befogged by acceptance as "epileptics" of many feeble-minded persons in whom seizures were a manifestation of gross developmental defect of the brain. Our purpose in the present communication is to describe the hereditary factors in a group of well adjusted, non-psychotic, nonfeeble-minded extramural persons with epilepsy and to determine whether these patients have a different heritage than institutional, deteriorated patients.

That hereditary factors play an important rôle in the etiology of epilepsy has been recognized by practically all writers. Thus Sieveking¹ found evidences of a neuropathic heredity in 11 per cent of cases, Reynolds² in 31 per cent, Eccheveria³ in 23 per cent, Berger⁴ in 32.3 per cent, Moreau⁴ in 32 per cent, Binswanger⁵ in 36.3 per cent, Dejerine⁶ in 66.8 per cent, Hammond⁷ in 28 per cent, Aronsohn⁸ in 32 per cent, Gowers⁹ in 40 per cent, Spratling¹⁰ in 56 per cent, Finckh¹¹ in 73 per cent, Siebold¹² in 55.2 per cent, Turner¹³ in 51 per

cent, Oppenheim¹⁴ in from 33 to 50 per cent, Kraepelin¹⁵ in 45.7 per cent, Starr¹⁶ in 35 per cent, Snell¹⁷ in 81.2 per cent and Muskens¹⁸ in 62 per cent.

The material used for this study consists of the records of 331 adult nondeteriorated patients with epilepsy.¹⁹ Of these, 266 were from the private practice of Dr. Hugh T. Patrick and sixty-five from the outpatient clinic of Northwestern University Medical School. In order to allow sufficient time for deterioration to occur, no patient was accepted for this study unless he had had seizures for at least six years. Of the 331 patients, 37.8 per cent had had the disease for from six to ten years; 24.3 per cent, eleven to fifteen years; 16.2 per cent, sixteen to twenty years; 8.9 per cent, twenty-one to twenty-five years; 6.1 per cent, twenty-six to thirty years, and 6.7 per cent over thirty years. Patients with defective mental development and with focal signs of neurologic disorder were not accepted for this study.

Of the 331 patients, 139, or 42 per cent, had an unimportant family history. In the remainder, or 58 per cent, there were evidences of a hereditary neuropathic taint.²⁰

21. Jordan, W. R., and Crabtree, H. H.: Paralysis of the Bladder in Diabetic Patients, Arch. Int. Med. 55: 17-25 (Jan.) 1935.
From the Department of Nervous and Mental Diseases, Northwestern University Medical School, and the Minnie Frances Kleman Memorial Fund.

The writer whose data regarding heredity may best be compared with ours is Snell.¹⁷ In 345 cases he found evidences of a familial neuropathic trend in 81.26 per cent, a ratio 23.2 per cent higher than that found in our series. From this it seems reasonable to believe that hereditary neuropathic taint is more frequent in deteriorated, institutional patients than in nondeteriorated, well adjusted patients in the outside world.

A further comparison of Snell's data regarding heredity with those of the present series disclosed some interesting differences. In our series a neuropathic factor could be detected in the direct line (parents) in 41 per cent, in the indirect line (grandparents, uncles and aunts) in 10.4 per cent and in siblings in only 6.6 per cent. In table 1 we have compared these data with those for institutional patients. This table shows that the nondeteriorated patients show a smaller percentage of hereditary taint in the direct and indirect line. In the siblings, tainting is more frequent in the nondeteriorated patients (6.6 per cent to 5.4 per cent), but the difference is so small as to be of no statistical significance.

In the direct line (parents) Snell found psychosis in 5.96 per cent, nervous disorders in 17.15 per cent, of which 4.94 per cent were epilepsy, alcoholism in 24.15 per cent, apoplexy in 5.39 per cent, senile dementia in 0.28 per cent, psychopathic personality in 10.79 per cent and suicide in 0.85 per cent. How these data compare with those obtained in the present series is shown in table 2. Migraine and nervousness were more common

personality; in Snell's institutional patients this ratio was 10.79 per cent. It thus appears that the parents of the more malignant, deteriorated, institutional patients with epilepsy are much more heavily burdened with neuropathy than are the parents of the nonpsychotic extramural epileptic persons.

TABLE 4.—The Percentage of Frequency of Epilepsy, Insanity and Alcoholism as Hereditary Factors in Patients with Epilepsy as Given by Some Authors and Noted in the Present Series of Nondeteriorated Epileptic Patients

	Epilepsy	Insanity	Alcoholism
Sieveking ¹	11.1
Echeverria ³	10.4
Dejerine ⁶	21.2	16.8	51.6
Féré ²¹	38.3
Starr ¹⁶	7.0	9.3
Hammond ⁷	16.1	12.1
Aronsohn ⁸	18.0
Voisin ⁶	31.0
Binswanger ⁵	11.0	20.6	22.0
Gowers ⁹	30.3	13.6
Doran ²²	19.3	7.9	21.6
Spratling ¹⁰	16.0	7.0	14.0
Finckh ¹¹	24.2	15.9	18.9
Turner ¹³	27.2	5.4	3.1
Kraepelin ¹⁶	14.3
Muskens ¹⁸	35.7	14.5	8.0
This series.....	8.4	3.5	4.3

A study of the entire families in the present series also disclosed some significant differences from data obtained from similar studies by Snell. In our series the 331 nondeteriorated patients had 375 relatives showing evidences of a neuropathic taint. Of these it was found that 4 per cent had a psychosis, 38.4 per cent had migraine, 32.3 per cent showed nervousness, 14.4 per cent had epilepsy, 4.8 per cent were alcoholic, 4.3 per cent had apoplexy, 1.3 per cent had psychopathic personality, 0.8 per cent were suicides, and 0.5 per cent were feeble-minded. A comparison of these data with those obtained from a study of 502 relatives of Snell's institutional patients showed some interesting differences (table 3). The relatives of the nondeteriorated patients had more migraine and nervous symptoms but in the relatives of the institutional patients psychosis was more than five times as frequent as in the relatives of the present series; alcoholism was more than five times as frequent, and apoplexy, psychopathic personality and suicide, one and a half times, ten times and three times as common, respectively, as in the relatives of sane patients with epilepsy. The relatives of the institutional patients had epilepsy in 11.75 per cent; the relatives of the nondeteriorated patients had this disorder in 14.4 per cent, a difference of but slight statistical significance. From this it seems that not only the parents but all relatives of institutional patients carry a heavier load of neuropathy than do those of the epileptic persons who adjust and succeed in the outside world.

Most other writers on the heredity of persons with epilepsy have looked for the presence of epilepsy, insanity and alcoholism mainly in the families of their patients. Some paid attention to all three conditions and others to but one or two. In our series of non-deteriorated patients with epilepsy, epilepsy was found in the family in 8.4 per cent, insanity in 3.5 per cent and alcoholism in 4.3 per cent. How these figures compare with similar data of other writers is shown in table 4. A study of this table shows that figures for these values as given in the literature far exceed those

in the parents of the nondeteriorated patients, but psychosis was more than five times as frequent in the institutional patients as in the extramural ones, epilepsy more than three times as frequent, alcoholism more than eight times as frequent and apoplexy more than twice as frequent. In our series there were no patients whose parents had senile dementia or who had committed suicide, while in Snell's institutional patients senile dementia and suicide were not rare. In our series 0.6 per cent of the parents had psychopathic

21. Féré, Charles: Les epilepsies et les épileptiques, Paris, Felix Alcan, 1890.
22. Doran: Am. J. Insanity 160: 61, 1903.

obtained in the present study with two exceptions: Starr found that in his patients there was a history of epilepsy in the family in 7 per cent, or 1.4 per cent less than we found, but his patients were from private practice and outpatient clinics. Turner found alcoholism in 3.1 per cent of his patients, a value 1.2 per cent lower than ours. This table affords further evidence of the differences in heredity between patients institutionalized because of mental changes and those who are well adjusted outside an institution.

CONCLUSIONS

Studies of the hereditary factors in epilepsy have heretofore been gathered almost exclusively on the deteriorated institutional patients with epilepsy. These represent only those epileptic patients in whom mental changes developed necessitating commitment. The great numbers of nondeteriorated patients with epilepsy who do not deteriorate and who adjust and succeed in the outside world have heretofore played little if any rôle in the estimation of the hereditary factors in this disease. A study of the hereditary factors in a group of nondeteriorated, well adjusted, extramural patients with epilepsy indicates that they come of a stock carrying a lighter burden of neuropathy than do the deteriorated, institutional patients.

HYPOGLYCEMIA WITH PARADOXICAL SUGAR TOLERANCE CURVE SIMU- LATING PEPTIC ULCER

A. ROBERT PESKIN, M.D.

Adjunct Attending Physician, Beth Israel Hospital; Assistant Visiting
Physician, Gouverneur Hospital

NEW YORK

Advances in biochemistry have shown that the behavior of human beings is in a great degree dependent on the stability of metabolic processes. If the metabolism of an individual is in some manner disturbed, he responds with a reaction entirely abnormal and is said to be suffering from a "disease."

The importance of metabolism is generally known, yet the progress in our knowledge of infectious diseases and bacteria have in some way relegated the metabolic disorders into the background of clinical values. Disorders of metabolism produce symptom complexes as variable as individuals in their constitutional make up. Human beings are particularly sensitive to humoral changes. Such changes as excessive intake or loss of water will produce abnormal reactions. Changes in the mineral or colloidal constituents of the body, such as loss of salts or plasma proteins, will produce varied clinical pictures. An excess of sugar, as well as a lack of sugar, is reflected in a particular symptom complex.

The degree of variance that will bring forth an abnormal response differs among individuals. A drop in the sugar level of the blood plasma of one human being may not play as important a rôle in the clinical picture as a similar drop in another. The critical level of change in the constituents of the body humors is characteristically individual. To illustrate this point, three cases are cited.

Mr. Jack Center, B.Sc., gave valuable assistance in the preparation of this paper, particularly with reference to the laboratory work. Dr. S. N. Weber offered helpful suggestions, and the author was assisted by Drs. Offerman, Lust and Maraffino and Mr. Heifetz, his associates of the Gastro-Intestinal Clinic of Gouverneur Hospital.

REPORT OF CASES

CASE 1.—History.—A white man, aged 35, presented himself because of pain in the epigastrium, severe in character and cramplike in nature. These symptoms occurred about two or three hours after meals and were relieved by the ingestion of food. Alkalis, however, were never efficacious. The pain would awaken him from sleep four or five times nightly. Sleep could be resumed only after the patient had partaken of some food. It is interesting to note that he was afforded instantaneous relief not only by bland foods but by sharp, spicy foods as well. If for some reason food was not available, he experienced a cold sweat, faintness, weakness and marked nervousness. There was no nausea, heartburn or vomiting present. At no time did he notice tarry stools. The pain was not localized but spread over the entire abdomen and was felt to start in the epigastrium.

Although this history dated back ten years to the onset, there were periods of complete remission of symptoms. Recurrence of attacks, while not distinctly seasonal, suggested certain periodic frequency. The patient felt that each attack was brought on by some indiscretion in diet, although alcohol was well tolerated. For a few weeks prior to his appearance for consultation the patient experienced marked nervousness, irritability, profuse sweating, marked twitchings, palpitation, shortness of breath and a sensation of heat. The outstanding symptom was an insatiable appetite, relieved only by frequent intake of food. This craving, if not satisfied, would result in severe abdominal pain.

The past history did not indicate any causative factors. The family history revealed no important facts bearing on this particular condition.

Physical Examination.—The patient appeared slightly over-nourished, nervous and apprehensive, with twitchings of the facial muscles and shoulders. Warm, moist hands with a fine tremor in the fingers were evident. There was a profuse sweat over his face and an anxious, glassy stare in his eyes. The pupils were slightly dilated, but equal and regular, and reacted to light and in accommodation. The eyegrounds were normal. There was a slight lid lag.

The blood pressure was 150 systolic, 110 diastolic. Heart sounds were regular in rate, rhythm and force, with no murmurs audible and not enlarged to percussion. The lungs showed no evidence of pathologic change. Abdominal exam-

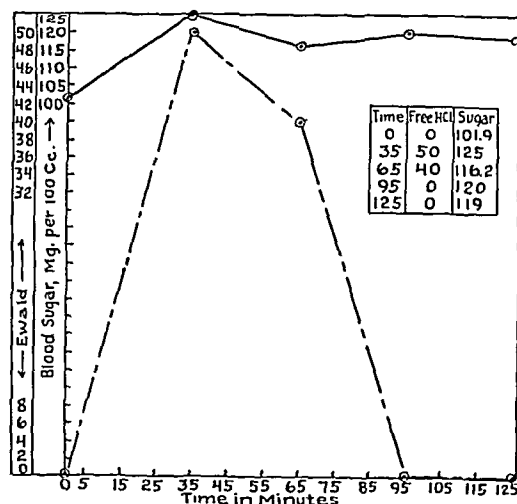

Chart 1 (case 1).—Free hydrochloric acid and blood sugar curves after 200 cc. of 5 per cent ethyl alcohol. Note blood sugar tolerance test, with simultaneous Ewald fractional gastric analysis.

ination elicited no palpable masses and no tender areas. The extremities were normal. Reflexes were slightly hyperactive.

Laboratory Examination.—Gastro-intestinal study disclosed the stomach and duodenum normal in size, shape, position and contour. There was, however, marked hypermotility of the stomach. The duodenal curve was moderately exaggerated. This was interpreted as possibly due to an abnormally large head of the pancreas.

Stool examination revealed no evidence of blood.

Examination of the gastric contents on a fasting stomach after a test meal of 200 cc. of 5 per cent ethyl alcohol plus five drops of methylene blue disclosed the free and total acid curves shown in chart 1.

Blood sugar determination showed a fasting blood sugar of 115 mg. per hundred cubic centimeters of blood. A sugar tolerance test determined by giving the patient 50 Gm. of dextrose on a fasting stomach and then determining the blood sugar level at half-hour intervals for two hours disclosed readings of 115, 85, 95 and 99.5 mg. per hundred cubic centimeters of blood (chart 2).

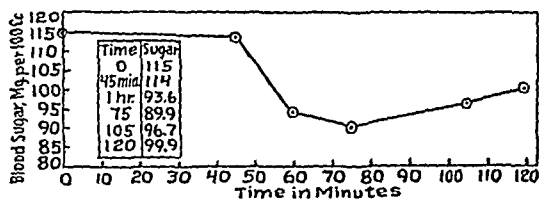

Chart 2 (case 1).—Sugar tolerance test: blood sugar curve after 50 Gm. of dextrose. Note the downward slope of the curve instead of the normal upward slope.

The basal metabolic rate revealed readings of plus 29 and plus 32 respectively. These figures were obtained before treatment was started. After one week under treatment, examination was repeated and a reading of only plus 4 was obtained.

The blood count gave normal results in all its phases.

Urine examination was negative for any pathologic constituents.

CASE 2.—A woman, aged 20, presented herself with a history of sharp, generalized epigastric pain. For the past two years this pain recurred every two hours and was relieved by foods but not by alkalis. It mattered little as to the type of food. Highly seasoned foods, condiments or alcohol were just as efficacious. Sweets in the form of candy were never observed to be helpful. The patient was short and of a hypopituitary type. Physical examination did not disclose other pertinent manifestations.

Complete laboratory examination revealed nothing relevant with the exception of the following:

1. Fractional gastric analysis disclosed a distinct hypo-acidity.

2. A gastro-intestinal series showed a perfectly normal stomach and duodenum.

3. The sugar tolerance test showed a fasting blood sugar of 67. One hour after the administration of 100 Gm. of dextrose the blood sugar dropped to 62 mg. Two hours after the administration of sugar it dropped to 53 mg. and the three hour specimen gave a reading of 50 mg. per hundred cubic centimeters of blood.

The patient responded poorly to the Sippy diet, carbohydrate diet and protein foods. However, on a high cholesterol diet the symptoms promptly subsided with no recurrence of the complaint. A repeated sugar tolerance

test after treatment by a high fat diet disclosed a normal curve (chart 3).

CASE 3.—A young woman presented herself with complaints similar to those of the second patient.

Physical examination was entirely negative.

Laboratory examination revealed:

1. Absence of gastric or duodenal lesions on x-ray examination.

2. Acid curves showing distinctly low values for the free and total acidity.

3. A bizarre sugar tolerance curve showing a fasting blood sugar of 85 mg. per hundred cubic centimeters of blood. One

hour after the administration of 100 Gm. of dextrose it rose to 94 mg. It then suddenly dropped to 54 at the two hour specimen and at the three hour examination gave a reading of 63 mg. per hundred cubic centimeters of blood.

The foregoing cases are some of a group that have been observed in our clinic for the past two years. These were chosen because they resembled most closely a condition which has been observed to be confused with and which simulates peptic ulcer. It is not unusual for one who has the privilege of seeing a large number of cases of gastro-intestinal disorder to be confronted with a group of patients who have symptoms interpreted as those of peptic ulcer and in whom roentgenologically no evidence of such ulcer is disclosed. Peculiarly enough, these patients respond to treatment by bland diet in the same manner as those with true ulcer, yet there are substantial differences in the behavior of the former group of patients as compared with the latter:

1. While the pains are relieved by frequent feedings, the diet may contain highly spiced and seasoned foods which are anathema to the true ulcer. Foods such as highly flavored sauces, condiments and alcohol are tolerated. Alkalis, on the contrary, do not offer relief.

2. While periodic frequency and seasonal recurrence of pains are associated with the true ulcer, they are not characteristic of this condition.

3. These patients bear their pain continuously, while it is infrequent for a true ulcer, except in the chronic, calloused, penetrating type, to cause unremitting pain throughout the year.

4. A more distinguishing characteristic of this group is the recurrence of pain four or five times a night, from which relief is to be had only after the ingestion of food.

5. While hyperacidity is a frequent accompaniment of peptic ulcer, as seen in chart 1, these patients show a decided tendency to diminution in acidity even to the point of achlorhydria.

While the differences outlined distinguish these two groups of cases as distinct entities, a still more positive and characteristic finding of the first group is its tendency to hypoglycemia. This hypoglycemia is elicited particularly on the administration of sugar. The normal individual, as well as the ulcer patient, responds with the usual orthodox positive curve on administration of 50 or 100 Gm. of sugar on a fasting stomach, while this particular group of patients displays a unique response. The curve takes on a definitely negative characteristic; i. e., instead of the sugar level rising and reaching its maximum at the end of from one and a half to two hours and then receding to normal, the curve in this group descends to a low level of 85 at the end of one and a quarter hours and then gradually ascends, never attaining the normal. While 85 mg. per hundred cubic centimeters of blood is not quite a hypoglycemic condition, still in some patients it may be sufficiently low to provoke symptoms of hunger and cramps. Again, it is not so much the hypoglycemia but the tendency

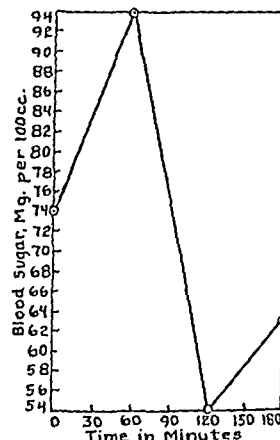

Chart 4 (case 3).—Sugar tolerance curve after 100 Gm. of dextrose, May 28, 1935.

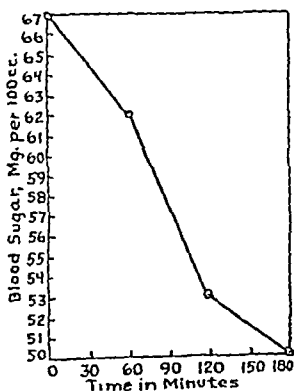

Chart 3 (case 2).—Sugar tolerance curve after 100 Gm. of dextrose given by mouth, July 11, 1935.

toward it, or the hypoglycemic curve initiated by the administration or ingestion of dextrose, which especially singles out these patients.

It may be assumed from the reaction of this group of patients to the sugar tolerance test and from the display of symptoms when the sugar level falls below a certain critical point that these patients differ from the normal in two distinct respects: first, their abnormal response to the ingestion of sugar and, second, their relationship to the critical level of blood sugar content at which symptoms are evidenced, which in this group of patients is higher than in the normal. These patients, unlike normal individuals who can adjust themselves with a certain degree of equanimity to changes in the blood sugar level, are prone to respond violently when their critical level is reached.

No attempt is made here to explain this apparently interesting observation. It may very well be that these individuals are constitutionally the subjects of an overactive pancreas or that they respond with an excessive overproduction of insulin on the ingestion of carbohydrates. Also it may be possible that in these patients carbohydrates are not converted into glycogen by the liver but instead are oxidized at once in the tissues. On the other hand, it is just as likely that glycogenesis takes place in a normal manner but that there may be some difficulty in the conversion of glycogen from the liver into available sugar. Just as the action of insulin is a moot question, so is the biochemical process involved in this particular observed anomaly.

That there is in this condition an increase in the oxidative processes of the body is shown by the high metabolic rate and the symptoms of tachycardia, excessive sweating, tremor, nervousness and eye symptoms—true indications of a hyperactive thyroid. Yet, one need not necessarily construe causal relationship between these symptoms and exophthalmic goiter, for it is quite conceivable that an increase in the oxidative processes of the body need not necessarily be the result of hyperthyroidism. As it happens in this case, the rapid oxidation of dextrose due to an oversecretion of insulin, with a consequent increase in the metabolic rate, may very well simulate an overactive thyroid but be entirely independent of it. In the present status of the knowledge of internal secretion, one cannot tell how great a part an overactive pancreas may play in calling forth an overactivity on the part of the thyroid.

It is not entirely without evidence, however, that one attributes the symptoms of increased metabolism to an overactive pancreas rather than to an overactive thyroid, for in the management of these cases it was observed that no particular attention to the thyroid was necessary to alleviate these so-called thyroid symptoms. Simple avoidance of overstimulation of the islets of Langerhans by withdrawal of carbohydrates from the diet definitely reduced the metabolic rate to plus four within a short while. Furthermore, even the administration of a diet high in proteins maintained a high metabolic level. This was interpreted as being the result of two factors: (1) the specific dynamic action of proteins themselves in raising the metabolic rate, and (2) the fact that proteins contain 52 per cent of carbohydrates, which in itself is sufficient to overstimulate the pancreas. Furthermore, when these patients were placed on a diet poor in carbohydrates and proteins and high in fat content, the basal metabolic rate was at once seen to drop and all the patient's symptoms were ameliorated. It is surprising to see with what gratification these patients, after years of unsatisfac-

tory treatment for ulcer, report complete relief from symptoms.

Just how the administration of a high fat diet can explain the reduction in the basal metabolic rate and the alleviation of symptoms in these patients is not clear. Much biochemical study, as well as further clinical observation, remains to be done to elucidate many points in this interesting clinical picture. While an insufficient number of cases have been studied, this case serves to bring to the attention of the profession a condition which demands consideration and thought whenever one encounters a peptic ulcer which is resistant to the ordinary orthodox treatment. Patients who present themselves with symptoms of peptic ulcer, in whom roentgenologic evidence is lacking, should always be studied from the point of view of a possible metabolic disorder of the nature described.

Not too infrequently is the roentgenologist blamed for disagreeing with the clinician when he cannot find definite evidence of an ulcer. Still more frequently is he coerced into reporting an ulcer by the insistence of the clinician or the suggestiveness of the history. It is hoped that, with time, developments will provide more basic evidence on these significant observations.

CONCLUSIONS

1. In cases of hypoglycemia with an abnormal response to sugar tolerance tests there was a similarity of symptoms produced by this condition with the symptoms of peptic ulcer.

2. There are criteria which distinguish this condition from peptic ulcer.

3. Further work on this condition is to be reported.
66 Park Avenue.

METHYL CHLORIDE (REFRIGERATOR) GAS POISONING

AN INDUSTRIAL HAZARD

ALBERT WEINSTEIN, M.D.

NASHVILLE, TENN.

Methyl chloride gas is one of the most popular refrigerants used in mechanical refrigeration. Poisoning by this gas attracted sufficient attention in 1929 to warrant an investigation by the American Medical Association. During that year, in a relatively short period, the occurrence of twenty-nine instances of this form of intoxication in Chicago was reported.¹ Ten patients of this group died. The report of the Committee on Poisonous Gases of the American Medical Association² included certain recommendations for the control of that hazard. It may be inferred from the sparsity of reports³ of poisoning by methyl chloride since that time that the advice of the committee had been followed. The appearance of two new cases of methyl chloride poisoning, however, emphasizes the fact that this industrial danger still exists.

REPORT OF CASES

Two white men, 44 and 28 years of age, were engaged in repairing an air conditioning plant located in the basement of a business concern. Ventilation was poor but considered adequate. After two hours of work the older patient noted headache, dizziness and fatigue. He accordingly quit work. The younger man continued to work an additional two hours, at the end of which time he too was forced to stop.

CASE 1 (aged 44).—When seen four hours after exposure, the patient was apathetic but answered questions intelligently. There was no cyanosis or dyspnea. He was nauseated, had vomited, and was having cramping abdominal pain. His temperature was 98 F. and his pulse rate was 96. The blood pressure was 134 mm. of mercury systolic and 80 diastolic. He was having attacks of vertigo, during which he shielded his eyes with his hands, and his face became flushed. However, no changes were noted in either the blood pressure or the pulse rate. The neurologic examination was negative except that there was a coarse tremor of the hands. The general examination likewise revealed no abnormalities save for an odor of the breath similar to that of chloroform. Urine examination revealed an acid specimen with a specific gravity of 1.010; tests for albumin and sugar were negative. The patient was given large amounts of bromide by rectum and spent a comfortable night. The following day he was free from complaints save for occasional attacks of vertigo.

The erythrocytes numbered 5,650,000 per cubic millimeter of blood; hemoglobin 18 Gm. per hundred cubic centimeters; leukocytes 8,100, 54 per cent of which were neutrophils, 7 per cent monocytes and 39 per cent lymphocytes. The fixed smear revealed definite anisocytosis with larger cells in preponderance. The blood nonprotein nitrogen was 28 mg. per hundred cubic centimeters. The icterus index was 3 and the van den Bergh test resulted in a very slight delayed reaction. A urine specimen contained 25 mg. of formic acid per liter. Three days later the patient was well enough to return to work although he felt very weak. This susceptibility to fatigue continued for approximately seven days. Examination then revealed no abnormalities.

CASE 2.—The second patient was seen at his home five hours after the onset of symptoms. He was desperately ill. Abdominal pain occurred in paroxysms and caused him to scream. He had attacks of vertigo every few minutes. These seizures, as in the first patient, were associated with flushing of the face, nausea and vomiting, but there was no change in the pulse rate or blood pressure. There was no cyanosis. Babinski's sign was present bilaterally and the deep reflexes were hyperactive. No other neurologic abnormalities were noted. The abdomen was rigid; the blood pressure was 130 systolic and 80 diastolic. The temperature was normal and the pulse rate 120. The odor of the breath was impressive and of the same character as noted in the first case.

He was given two doses each of morphine 15 mg. ($\frac{1}{4}$ grain) and atropine 0.4 mg. ($\frac{1}{40}$ grain) but no relief was obtained. Accordingly he was admitted to the Nashville General Hospital, where he received morphine (15 mg.) again and calcium chloride (1 Gm.), intravenously, together with a hypodermoclysis of 2,000 cc. of physiologic solution of sodium chloride.

The specific gravity of the urine was 1.017, and no albumin or sugar was present. The erythrocyte count was 4,300,000, hemoglobin 14.5 Gm. and leukocytes 8,650, of which 68 per cent were neutrophils. No abnormalities were noted in the fixed blood smear stained by Wright's method. The blood chemistry examination (expressed in mg. per hundred cubic centimeters) revealed nonprotein nitrogen 44, sodium chloride 338, sugar 90, calcium 15. The carbon dioxide combining power of the plasma was 37 volumes per cent. Lumbar puncture revealed the cerebrospinal fluid pressure to be 120 mm. of water. The fluid contained 8 cells and gave negative globulin and Wassermann tests. A urine specimen contained 19.2 mg. of formic acid per liter.

The condition of the patient remained essentially unchanged for twenty-four hours. He continued to experience severe paroxysms of pain in spite of the free use of morphine. During the first two days of the illness his temperature varied between 99 and 100. He became slightly jaundiced; the icterus index was 10 or above for four days. Because of acidosis and hypochloremia, 3 per cent sodium bicarbonate solution and 10 per

cent dextrose in saline solution were given intravenously. Since he apparently was excreting some product of the gas through the expired air, rebreathing exercises with 5 per cent carbon dioxide were employed every three hours. This was continued for three days until the odor of the gas had disappeared. The blood sodium chloride content rose on the third day of hospitalization to 495 mg. per hundred cubic centimeters and the nonprotein nitrogen returned to normal. The carbon dioxide combining power rose to 50 volumes per cent.

There was no evidence at any time of suppression of urine and there was no diarrhea.

After three days the Babinski's signs, hyperreflexia, paroxysms of vertigo, nausea, vomiting and abdominal pain disappeared. He remained in bed a total of eight days, at the end of which time the physical examination gave normal results save for moderate tachycardia and slight elevation of the diastolic blood pressure.

COMMENT

Methyl chloride gas was the cooling agent used in the air conditioning plant which these men repaired. This gas is extensively used as a refrigerant. It has many advantageous features besides its low boiling point ($-23.7^{\circ}\text{C}.$); it is stable, noncorrosive to metals, relatively noninflammable, nonexplosive, noninjurious to foods, furs or textiles, and may be used in low pressure systems. Unfortunately the gas is absolutely nonirritating and practically odorless. Thus the victim of exposure is poisoned without warning.

After the initial report⁴ in 1914, poisoning by this gas was noted very infrequently until 1927. Baker⁵ in 1927 reported twenty-one cases observed among workers in a refrigerating plant in Evansville, Ind. The symptoms in order of frequency of occurrence were drowsiness, vertigo, staggering gait, mental confusion, a feeling of "walking on air," ptosis of the eyelids, anorexia, nausea, visual disturbances, dysphagia, hiccup and tremors. In the most severe cases reported, convulsions occurred. Most of the patients completely recovered in from fourteen to twenty-one days, although one had a persistent foot drop. Because the gas was similar chemically to methyl alcohol, which is excreted in part as formate in the urine, Baker tested the urine of these patients and found formic acid present.

In 1929 Kegal, McNally and Pope¹ reported a group of twenty-nine cases in which poisoning occurred as the result of a leaking refrigerating system in Chicago apartment houses. Ten of these patients died. The symptoms of the more severe cases resembled acute food poisoning. The characteristic postmortem changes were pulmonary edema, dilatation of the heart, areas of degeneration in the liver and kidneys, and petechial hemorrhages scattered throughout the pleura, endocardium and dura.

Following this report the American Medical Association in 1930 appointed a committee to investigate the problem. The committee criticized all the commonly used refrigerants—ammonia, sulfur dioxide, carbon dioxide, ethyl chloride and methyl chloride—and recommended the development of a nontoxic gas; in addition it urged the adoption of a national code of supervision for refrigeration plants.

It is apparent that the ideal refrigerant has not been discovered. The experience with the patients reported herein indicates that supervision of installation and operation of refrigerating plants is not universally practiced. There is nothing to indicate that state or federal health agencies have attacked this important industrial and domestic health hazard. Recently a nontoxic

5. Baker, H. M.: Intoxication with Commercial Methyl Chloride. J. A. M. A. 88: 1137-1138 (April 9) 1927.

refrigerant, dichlorodifluoromethane, has been developed, but I have been unable to discover the present extent of its use. Certain manufacturers have added small amounts of irritating gases (1 per cent acrolein [methyl chloride-A, E. I. Dupont de Nemours & Co.]), to refrigerants employed by them, so that individuals exposed to its dangers may be aware immediately of its presence. As pointed out by the committee of the American Medical Association, such warning agents are useful in the case of normal adults but do not guarantee safety and are of little or no value to infants, invalids, the insane, or persons under the influence of alcohol.

As has been emphasized, pure methyl chloride is odorless. The odor of the breath of patients poisoned by methyl chloride is characteristic and it persists for some time after the exposure to the gas (for four days in one of our cases). It is strikingly similar to that of chloroform. In considering the source of this odor, the possible products of oxidation and hydrolysis of the gas have been reviewed. It seems likely that the odor is due to either methyl alcohol (CH_3OH), formed as the result of hydrolysis of the methyl chloride (CH_3Cl), or acetone associated with the acidosis, or both. Such an explanation is compatible with the clinical observation that early symptoms of poisoning simulate those induced by the inhalation of an anesthetic gas and the late manifestations resemble those of methyl alcohol intoxication. Partial oxidation of methyl alcohol to formic acid (HCOOH) and its excretion by the kidney constitute an explanation for the presence of formic acid in the urine. It has been shown⁵ that the quantity of formic acid excreted parallels the severity of the intoxication.

These cases are reported as important examples of industrial poisoning. The hope is entertained that, by diffusing knowledge of this hazard, incapacitation and even death may be prevented. It is desirable that the hazards of mechanical refrigeration should come under the supervision of official public health agencies.

SUMMARY

1. Two new cases of poisoning by methyl chloride (refrigerator) gas were observed.
2. Methyl chloride poisoning constitutes a hazard to which there is extensive exposure.
3. Federal, state and local health agencies should exercise effective control of refrigerants.

Mountains and Sun Baths.—The sun bath being always inseparable from the air bath, the quality of this air ought necessarily to play an important part. It is easy to understand that if the sun bath is taken in a stimulating air its action will be much more favorable. On the contrary, if the sun bath is applied in a heavy air, its action will be depressing on the organism. For that reason the treatment by natural sunlight practiced in the mountains is particularly efficacious. One knows, on the other hand, that the radiation from the sun is more intense at an altitude where the air is purer than in the plains where the damp, dust and smoke absorb a part of the sun's rays. Another advantage in the mountains is that the sun bath can be taken at all seasons. If the use of the natural light in winter is impossible in the plains, this season is especially favorable in the hills, where the sun shines without interruption during long intervals, and where the intensity of these rays is increased by the reflection on the snow. It goes without saying that heliotherapy will be more efficacious there if it is applied in places well situated, protected from wind, and well organized for sun treatment.—Rollier, Auguste: *Natural Sunlight in the Treatment of Tuberculosis*, *M. Press & Circ.* supplement, Sunlight, April 7, 1937, p. 9.

Clinical Notes, Suggestions and New Instruments

SUBCUTANEOUS RUPTURE OF THE TRACHEA

ALOYSIUS P. RIEMAN, M.D., JERSEY CITY, N. J., AND ALFRED S. GOLDSMITH, M.D., NORTH BERGEN, N. J.

Perforating wounds of the trachea due to indirect injury are unusual. References in the surgical literature are few, particularly when a cure has followed treatment. Recently Tixier¹ reported a case from France which resulted from an automobile accident five hours previously. The trachea was found completely severed transversely, in addition to a longitudinal posterior tear. The patient died sixty hours after operation. Graham¹ mentions four cases in which recovery followed the treatment that was instituted.

REPORT OF CASE

T. R., a white boy aged 7 years, was brought to the hospital July 31, 1936, following a fall from a bicycle in which the lad struck his neck against the handle bars. On admission he was markedly cyanotic. Subcutaneous emphysema was most pronounced, extending from the head to the knees. The nurse's notes described the patient as being "ballooned out." His past medical history and family history were irrelevant. The emphysema was so marked in the head that the eyelids bulged forward, completely occluding the eye. The contour of the neck was lost. Of interest was the fact that there was no external evidence of trauma. Another interesting feature was the fact that the respiratory and pulse rates were not unduly elevated, being 22 and 110, respectively. The temperature was 99.4 F. by rectum. It was felt that the trachea was torn and that air was being forced into the subcutaneous tissues.

The patient was immediately taken to the operating room for tracheotomy. After infiltration with 1 per cent procaine hydrochloride, a midline incision was made from the level of the hyoid to the episternal notch. The soft tissues were retracted and hemostasis was observed. Exploration revealed an opening in the right side of the trachea about 1 cm. below the cricoid cartilage in the region of the third tracheal ring. It was situated laterally so as to be contiguous with the carotid sheath. It was felt that the opening would heal if the air had a greater outlet nearby. During the exploration the patient became unexpectedly irrational and profoundly cyanosed, and suddenly ceased to breathe. A tracheotomy was quickly performed, which included the second and third cartilaginous rings. Artificial respiration was instituted, and with dramatic suddenness the patient's color returned as his respiration resumed its function. A drain was placed down to the lateral opening in the trachea, and the soft tissues were approximated in the usual manner. A firm outer dressing was applied.

The postoperative course was uneventful. The child was placed in a warm room. During the next six days, feedings were accomplished by means of a Levine tube passed through the nose to the stomach. After this time his general condition permitted feeding in the usual manner. The inner tracheal tube was kept patent by periodic removal and cleansing. Suction was used to remove the accumulated mucus from the tracheal tube and lower part of the trachea. The tube was removed on the twelfth postoperative day, after testing to assure a patent airway. No difficulty with respiration was encountered. The subcutaneous emphysema disappeared rapidly, at first from the face and upper extremities, and later from the chest and abdomen. By the sixteenth postoperative day, only a little emphysema was present in the scrotum. This terminal emphysema disappeared in another two to three days. By the twenty-sixth postoperative day the wound had healed and the patient was discharged cured. He has remained entirely well since then.

From the Surgical Service of the North Hudson Hospital, Weehawken, N. J.

1. Tixier, in *Yearbook of General Surgery*, E. A. Graham, editor, 1936, p. 179.

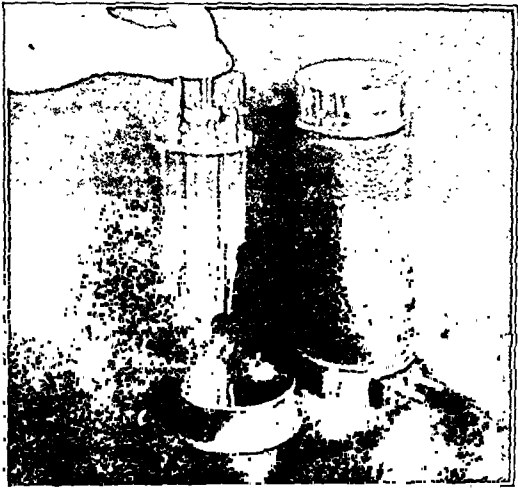

SUMMARY

In a case of subcutaneous rupture of the trachea following an indirect injury, a cure resulted after tracheotomy. Of especial interest in this case is the amount and extent of subcutaneous emphysema in its relation to the size of the tracheal rupture. A most unusual feature is the fact that there was no break in the skin, yet a small tracheal laceration resulted. It is this type of case which lends itself more satisfactorily to therapy than cases in which there is extensive trauma and little subcutaneous emphysema, as in the case of Tixier's mentioned previously.

A NEW TYPE PORTABLE STERILIZER FOR
SYRINGES AND NEEDLES

JAMES K. McSHANE, M.D., MIAMI, FLA.

This apparatus is an electric sterilizer for syringes, needles and minor operating kits. Being extremely portable and combining a method of not only sterilizing syringes and needles but also carrying them in a sterile condition, it permits the physician to have sterile syringes on hand at all times for any emergency or routine treatment in the patient's home that may be necessary. As it is smaller than a blood pressure apparatus this sterilizer can be carried at all times, and if necessary

Portable sterilizer for syringes and needles.

sterilization can be done in the patient's home. This, however, should be seldom necessary, as several sterile syringes and needles can be carried at the same time.

The sterilizer is a cylindric tube 6½ inches long and 2¼ inches in diameter and weighs 9 ounces. The base contains an electric unit which may be used on either alternating or direct current. As water is required to complete the circuit, it is entirely automatic in action and cannot burn out after boiling dry. The top is a friction cap containing a spring steam valve to allow the escape of steam, which is utilized in sterilizing the syringes and needles. Inside the case is a removable holder for placing the syringes and needles. The one illustrated holds one 10 cc. syringe, one 5 cc. syringe, two 2 cc. syringes and four needles of any size. Any combination of syringes can be carried by varying this holder.

METHOD OF OPERATION

The syringes are placed in the holder, which is then placed in the sterilizer. A minimum of 4 drachms of water is added, the lid replaced firmly and connection made with the electric circuit. Boiling occurs in less than a minute and is continued until all the water has been evaporated (usually twenty minutes or more), when the circuit is automatically broken. The sterilizer containing the now sterile syringes and needles can be placed in one's bag and is ready for instant use. By removing the carrier a 20 cc. syringe can be accommodated or catheters, rubber gloves and small operation kits can be sterilized and then carried in a sterile condition.

307 Ingraham Building.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT.
HOWARD A. CARTER, Secretary.

HIGH TENSION ELECTRO-SURGICAL UNITS
(MODELS C-920 AND C-975) ACCEPTABLE

Manufacturer: High Tension Corporation, 118 West Twenty-Second Street, New York.

These portable surgical units are designed for intermittent operation and are recommended for coagulation and desiccation. They may be used in hospitals, offices or other medical institutions. The evidence presented indicated that when units are

Fig. 1.—Model C-920
Electro-Surgical Unit.

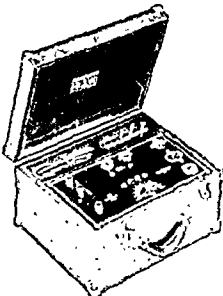

Fig. 2.—Model C-975
Electro-Surgical Unit.

operated under what may be regarded as actual clinical conditions the temperature rise of the transformer, the spark gaps or other essential parts was within the limits prescribed by the Council. The input power required for these units is between

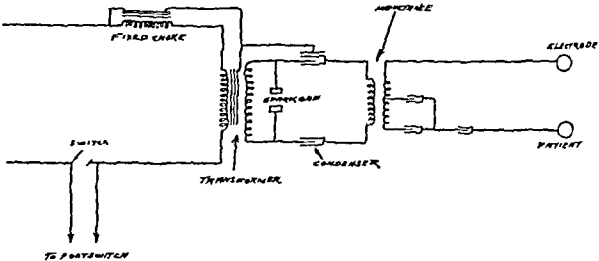

Fig. 3.—Schematic diagram of circuit (Model C-920).

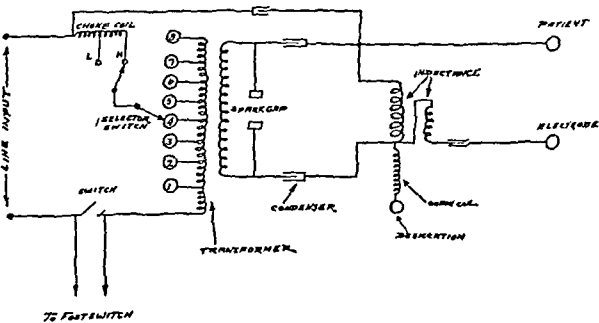

Fig. 4.—Schematic diagram of circuit (Model C-975).

135 and 230 watts. Their frequency is between 890 and 1,420 kilocycles per second, which corresponds to wavelengths between 211 and 37 meters. The investigator appointed by the Council used these units in a clinic acceptable to the Council and found them satisfactory when operated under actual clinical conditions.

In view of the favorable report, the Council voted to include the High Tension Electro-Surgical Units, Models C-975 and C-920, in its list of accepted devices.

THE ATLANTIC CITY SESSION

AMERICAN MEDICAL ASSOCIATION, EIGHTY-EIGHTH ANNUAL SESSION
ATLANTIC CITY, N. J., JUNE 7-11, 1937

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The eighty-eighth annual session of the American Medical Association will be held in Atlantic City, June 7-11, 1937.

The House of Delegates will convene at 10 a. m., Monday, June 7. In the House the representation of the various constituent associations for 1935, 1936 and 1937 is as follows:

Alabama	2	New Hampshire	1
Arizona	1	New Jersey	4
Arkansas	2	New Mexico	1
California	7	New York	17
Colorado	2	North Carolina	2
Connecticut	2	North Dakota	1
Delaware	1	Ohio	7
District of Columbia	1	Oklahoma	3
Florida	2	Oregon	1
Georgia	3	Pennsylvania	11
Idaho	1	Rhode Island	1
Illinois	9	South Carolina	2
Indiana	4	South Dakota	1
Iowa	3	Tennessee	3
Kansas	2	Texas	6
Kentucky	3	Utah	1
Louisiana	2	Vermont	1
Maine	1	Virginia	3
Maryland	2	Washington	2
Massachusetts	6	West Virginia	2
Michigan	5	Wisconsin	3
Minnesota	3	Wyoming	1
Mississippi	2	Alaska	1
Missouri	5	Hawaii	1
Montana	1	Isthmian Canal Zone	1
Nebraska	2	Philippine Islands	1
Nevada	1	Puerto Rico	1

The fifteen scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each.

The Scientific Assembly of the Association will open with the general meeting to be held at 8 p. m., Tuesday, June 8. The sections will meet Wednesday, Thursday and Friday, June 9, 10 and 11, as follows:

CONVENING AT 9 A. M., THE SECTIONS ON

Practice of Medicine.	Pathology and Physiology.
Obstetrics, Gynecology and	Preventive and Industrial Medicine and Public Health.
Abdominal Surgery.	Urology.
Laryngology, Otology and	Orthopedic Surgery.
Rhinology.	

CONVENING AT 2 P. M., THE SECTIONS ON

Surgery, General and Abdominal.	Nervous and Mental Diseases.
Ophthalmology.	Dermatology and Syphilology.
Pediatrics.	Gastro-Enterology and Proctology.
Pharmacology and Therapeutics.	Radiology.

The Registration Department will be open from 8:30 a. m. until 5:30 p. m., Monday, Tuesday, Wednesday and Thursday, June 7, 8, 9 and 10, and from 8:30 a. m. to 12 noon, Friday, June 11.

CHARLES GORDON HEYD, President.
NATHAN B. VAN ETEN, Speaker, House of Delegates.
OLIN WEST, Secretary.

MEMBERS OF THE HOUSE OF DELEGATES A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state associations are yet to hold their meetings at which delegates will be elected. The following is a list of the holdover members of the House of Delegates and of the newly elected members who have been reported to the Secretary in time to be included:

STATE DELEGATES

ALABAMA J. N. Baker, Montgomery. A. A. Walker, Birmingham.	LOUISIANA James Q. Graves, Monroe. W. H. Seemann, New Orleans.
ARIZONA J. D. Hamer, Phoenix.	MAINE William A. Ellingwood, Rockland.
ARKANSAS William H. Mock, Prairie Grove. William R. Brooksher, Fort Smith.	MARYLAND Alfred T. Gundry, Catonsville.
CALIFORNIA Elbridge J. Best, San Francisco. Lyell C. Kinney, San Diego. Fred B. Clarke, Long Beach. Charles A. Dukes, Oakland. Edward M. Pallette, Los Angeles. Robert A. Peers, Colfax. William R. Molony Sr., Los Angeles.	MASSACHUSETTS Charles E. Mongan, Somerville. Walter A. Lane, Milton. Richard H. Miller, Boston. Edmond F. Cody, New Bedford. John M. Birnie, Springfield.
COLORADO Harold T. Low, Pueblo. John W. Ames, Denver.	MICHIGAN L. J. Hirschman, Detroit. H. A. Luce, Detroit. T. R. K. Gruber, Eloise. J. D. Brook, Grandville. C. R. Keyport, Grayling.
CONNECTICUT George Blumer, New Haven. Walter R. Steiner, Hartford.	MINNESOTA J. T. Christison, St. Paul. W. A. Coventry, Duluth. W. F. Braasch, Rochester.
DELAWARE Stanley Worden, Dover.	MISSISSIPPI
DISTRICT OF COLUMBIA Henry C. Macatee, Washington.	MISSOURI W. H. Breuer, St. James. W. M. West, Monett. A. R. McComas, Sturgeon.
FLORIDA Herbert L. Bryans, Pensacola. Meredith Mallory, Orlando.	MONTANA J. H. Irwin, Great Falls.
GEORGIA Olin H. Weaver, Macon. William H. Myers, Savannah. Charles W. Roberts, Atlanta.	NEBRASKA B. F. Bailey, Lincoln. R. W. Fouts, Omaha.
IDAHO E. N. Roberts, Pocatello.	NEVADA Horace J. Brown, Reno.
ILLINOIS Charles J. Whalen, Chicago. John J. Plock, Chicago. G. Henry Mundt, Chicago. G. C. Otrich, Belleville. E. S. Hamilton, Kankakee.	NEW HAMPSHIRE Deering G. Smith, Nashua.
INDIANA Don F. Cameron, Fort Wayne. F. S. Crockett, LaFayette. H. G. Hamer, Indianapolis. R. L. Sensenich, South Bend.	NEW JERSEY Blase Cole, Newton. Ephraim R. Mulford, Burlington. Walt P. Conaway, Atlantic City.
IOWA Thomas F. Thornton, Waterloo. Vernon L. Treynor, Council Bluffs.	NEW MEXICO H. A. Miller, Clovis.
KANSAS	NEW YORK Nathan B. Van Eten, New York. Frederic E. Sondern, New York. Samuel J. Kopetzky, New York. George A. Leitner, Piermont. Carl Boettiger, Flushing. George M. Fisher, Utica. Charles H. Goodrich, Brooklyn. Floyd S. Winslow, Rochester. William D. Johnson, Batavia. Thomas P. Farmer, Syracuse.
KENTUCKY Virgil E. Simpson, Louisville.	

Edward R. Cuniffe, New York.
Grant C. Madill, Ogdensburg.
Thomas H. Cunningham, Glens Falls.
Frederick H. Flaherty, Syracuse.
James H. Borrell, Buffalo.
Terry M. Townsend, New York.
George W. Kosmak, New York.

* Deceased.

ATLANTIC CITY, 1937—THE WORLD'S PLAYGROUND

Endowed with extraordinary natural advantages, Atlantic City has developed from a small fishing village into one of the greatest pleasure and health resorts of all times, playing host each year to some twenty million visitors. Characterized as the "World's Playground," practically every type of activity desired can be obtained. Although nature has been bountiful, man has added to Atlantic City a long list of advantages and diversions.

SAILING AND FISHING

Speed boats, motor launches and other craft float on the waters of the Inlet waiting to take passengers for a cruise over the ocean or along the calmer waters of the thoroughfare that separates the resort from the mainland. Giant seaplanes also are available to carry passengers for a short scenic trip or on a hurried flight to some distant city. The Municipal Airport each season finds that an increasing number of guests has arrived by air.

Deep sea fishing off Atlantic City's coast has become increasingly popular and has made the city a mecca for sportsmen from all corners of the globe. The deep sea net haul takes

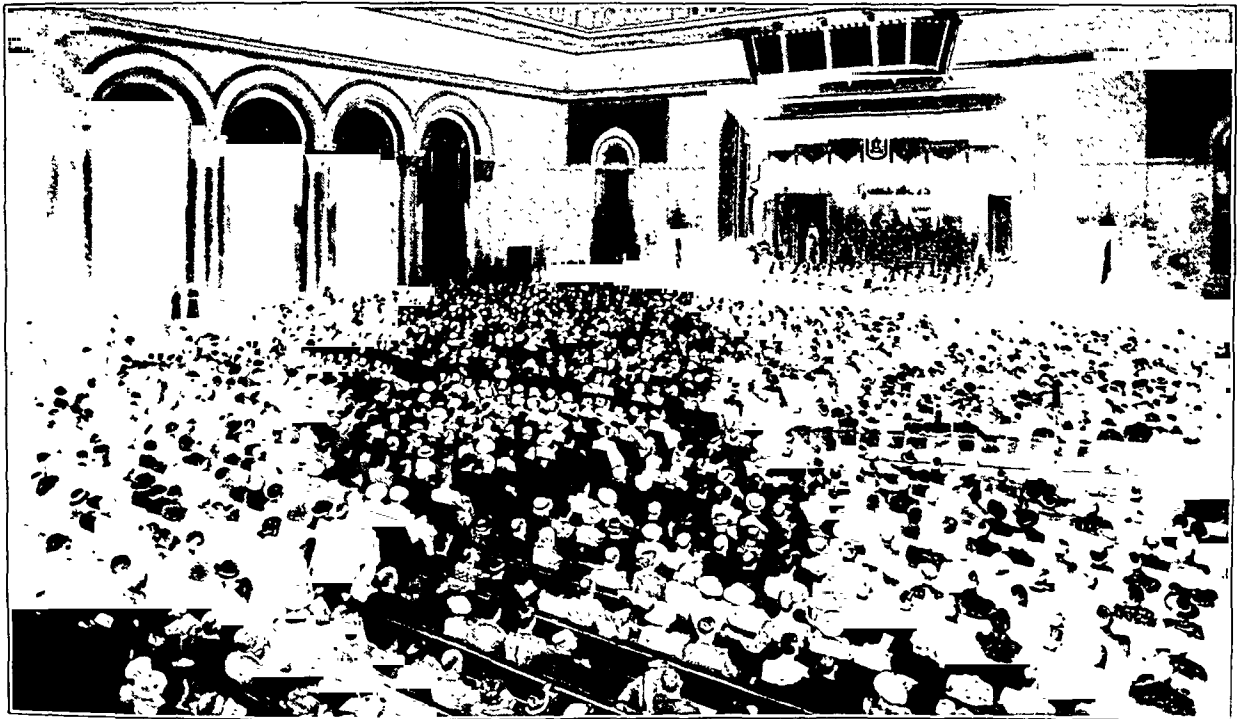

amusement devices for children are presented at the Steeplechase Pier, which features one of Atlantic City's two over-the-ocean restaurants; the other is on the Garden Pier, which also houses many amusements as well as a fine theater where legitimate shows and musical comedies frequently stage their openings before doing so on Broadway in New York. There are rare paintings, statuary and unusual discoveries of scientific excavation on exhibit at the historic Heinz Pier. The Central Pier is the home the year round of large national exhibits and of the Convention Bureau of Atlantic City.

THE BOARDWALK

Along the famous Boardwalk are five motion picture palaces which provide the visitor with early showings of current films; a legitimate theater offers special productions, while nationally known orchestras are featured in the restaurants, hotel grills, supper clubs and cafés.

HOTELS

The Boardwalk hotels are among some of the finest hotels in the world. They are skyscrapers along the beach, ready

OPENING GENERAL MEETING, ATLANTIC CITY AUDITORIUM IN 1935

place at noon and at 4 o'clock in the afternoon each day at the extreme end of Young's Million Dollar Pier, which jets out more than 2,000 feet over the ocean. All sorts of specimens of deep sea life are found in the catch, many exhibited later in the aquariums of Philadelphia, New York and Chicago. The pier's own aquariums are always filled with fish of every description. There are plenty of tuna and bluefish for those who wish to go farther to sea, and croakers, kings and weakfish for those who prefer to stay closer to shore. The Atlantic City Tuna Club has a new home on the back bay near Gardner's Basin, where it is ready to cater to all the demands of visiting fishermen.

AMUSEMENT PIERS

The great amusement piers in Atlantic City are among the most famous in the world. At the Steel Pier, a variety of attractions too numerous to visit in one day can be witnessed for a nominal admission. There are on the program famous stage, screen and radio stars, three motion picture houses, vaudeville, diving horses, acrobats, minstrels, dancing, water sports and other interesting attractions. Many of the latest

to cater to every wish of their guests, and at rates which are said to be lower than in years. The array of smart shops that string along the Boardwalk for miles display merchandise from all corners of the globe, and they as well as the hotels have collaborated in a reduction of prices to answer the challenge of other resorts.

THE CONVENTION HALL

The Convention Hall, in which the American Medical Association will hold its meetings, is the largest building of its kind in the world, covering an area of seven acres, fronting on the Boardwalk, between Georgia and Mississippi avenues. This huge building, erected at a cost of fifteen million dollars, has seating accommodations for nearly 75,000 persons, or more than sufficient to seat the entire permanent population of Atlantic City. Yet the Convention Hall is none too large, for at times during the summer there are as many as 400,000 visitors present in the city. The main auditorium alone has a seating capacity of 41,000 and a floor space of 168,000 square feet, with an additional space of 100,000 square feet provided on the ground floor. The Convention Hall is so large that

the well known Madison Square Garden of New York City could be placed in one corner of the main hall and a track meet and several large gatherings be staged at the same time in the remaining area. At the end of the auditorium is a large well equipped stage, capable of seating 5,000 persons. The immensity of the main auditorium may be visioned from the fact that a thirteen story building 500 feet long and 200 feet wide could be erected within its walls, leaving a space of 100 feet on all four sides.

ATLANTIC CITY SKY LINE

THE PIPE ORGAN

The largest pipe organ in the world is housed in the main auditorium of the Convention Hall. There are two giant consoles, one with seven manuals and the other, which is movable, with five, and 33,000 pipes ranging from three sixteenths of an inch to 64 feet in length. The organ has 1,255 stops and is run by a 365 horsepower group of motors. It has seven blowers and its own generator, and the wiring used in the organ would girdle the earth twice. Four years' time and \$500,000 were required to complete this great organ.

A striking feature of the hall is its versatility; the sheet of ice, 100 by 200 feet, frozen on the floor for skating, can be disposed of in a short time and a full sized indoor football field laid in its place. The lighting of the Convention Hall is a triumph of color and illumination, with the hues of the sea and the sky mingled with gold predominating. On the ground level are two well equipped bath houses 60 by 150 feet in area. The lobby leading to the Convention Hall has a vaulted passage 125 feet in length and 50 feet wide, with a ceiling of Gustavino tile and a two-tone terrazo floor. Leading from the lobby, and connecting with ramps to the upper and lower levels of the auditorium, are spacious corridors.

Stretching along the entire Boardwalk in front of the great Convention Hall is an arcade containing fourteen beautiful stores faced with marble and ornamental bronze; on the Pacific Avenue side of the building there are twenty-one additional stores. From the Arcade there leads off a wide entrance to the interior of the Convention Hall; about 400 automobiles may be parked on the ground floor of the Convention Hall. Wide terrace sidewalks have been provided on two sides of the building in addition to the ramps.

Ventilation and heating in a structure of this character are very important items. Ventilation is provided by thirty-one motor driven fans with a capacity of 1,600 tons of air per hour; there are also seventy-five vent fans capable of discharging 2,900 tons of air per hour. Seventy-two per cent of the air supplied to the Convention Hall is for the main auditorium. Direct radiation is the system used for heating the main entrance lobby and entrances on the side of the building. For the maintenance of the required vacuum in the heating returns and for the disposal of air and condensation, there are six vacuum pumps. The temperature throughout the building is automatically controlled. Three Sterling water boilers of 1,490 horsepower have been installed to provide

steam for heating, for hot water and for exhibition purposes. The oil fuel for this huge plant is stored underground in tanks; however, coal bunkers have been provided to make if necessary a quick change from oil to coal as fuel. Elevators capable of handling all kinds of heavy equipment have been installed. There are two large freight lifts each having a capacity of 50,000 pounds, in addition to an elevator of 4,000 pounds capacity for trunks and light freight, and a passenger elevator with a lifting rate of 300 feet a minute.

GOLF IN ATLANTIC CITY

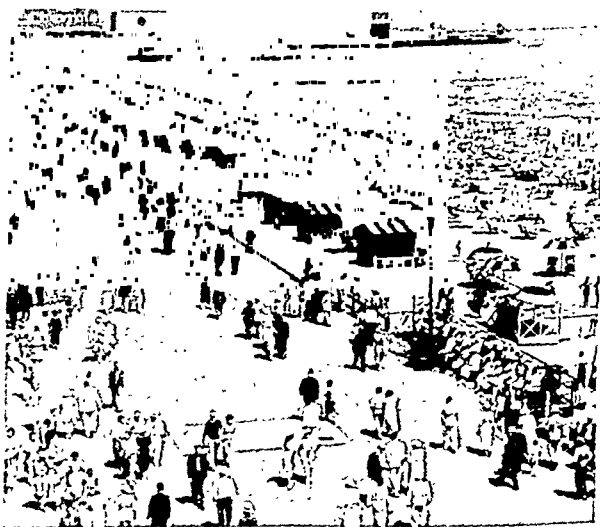

Five splendid golf courses, the Northfield and Linwood Country Clubs and the Brigantine, Ocean City and Seaview Golf Clubs, are only a few minutes ride from the heart of Atlantic City. For those who enjoy tennis, there are well equipped municipally owned courts at the Inlet and at the airport. Horseback riding may be enjoyed throughout the year; saddle horses and ponies for the children may be obtained at several stands along the beach. The wide eight mile stretch of beach makes a very beautiful bridle path.

ABSECON LIGHTHOUSE

Of great interest is the famous Absecon Lighthouse, which for years has served as a beacon to warn mariners of the treacherous Brigantine shoals. During certain hours visitors are allowed to walk up to the top of the Lighthouse, and the view out over the ocean is well worth the climb.

RESIDENTIAL SUBURBS

Atlantic City has two beautiful residential suburbs, Margate and Ventnor, where Spanish villas and colonial mansions, set in the center of great lawns, and typical American homes await amidst shrubbery and flowers the attention of visitors. It is to Margate and Ventnor and the Chelsea section of

THE BOARDWALK, CABANAS AND ONE OF THE PIERS
AT ATLANTIC CITY

Atlantic City that cottagers move for the summer months, and here will be found in these cottages persons who are famous in the annals of the theater, politics, art and society.

TRANSPORTATION FACILITIES

Atlantic City has unequalled transportation facilities, making it possible for millions of persons to pour in and out of the resort by motor, train, bus and airplane. No other resort in the world has such highways leading into it, and to no other resort is it easier for wheels to turn. The world's best known

highway, the "White Horse Pike," now has a twin, the "Black Horse Pike," to assist in aiding the millions to move in and out of Atlantic City. The Delaware River is crossed by five highway bridges from Philadelphia, north, and spanned by five important ferry routes from Philadelphia, south, draining the important areas to the South and West. In 1919 Atlantic City recognized the importance of commercial aviation and dedicated to it the first municipal airport in the world. By plane Atlantic City is five hours from Chicago, eight from Kansas City, one to Newark, two to Washington, and less than three to Pittsburgh. The resort's airport is one of the finest in the country.

GARAGES

There is a garage in the Convention Hall directly under the arena and the assembly hall, which will be a great con-

venience to those who are driving to the annual meeting of the American Medical Association. This garage will accommodate about 500 cars, and a special rate will be made for the period of the convention.

JITNEY SERVICE

There is a jitney service along Pacific Avenue from Maine Avenue to Jackson Avenue, the border of Ventnor.

ROLLING CHAIRS

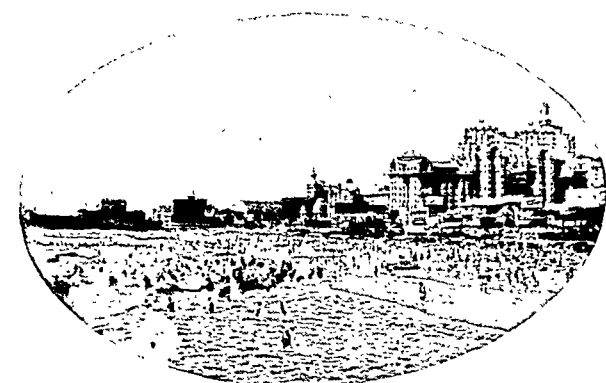

Special rates will be granted on rolling chairs to persons wearing convention badges. There will be a nominal charge for one, two or three passengers between Seaside Hotel and Convention Hall, or between Hotel Chelsea and the Convention Hall.

TRANSPORTATION

Railroad Rates to Atlantic City

Because of the reduction in one way fares to two cents a mile for tickets good in coaches and to three cents a mile in sleeping or parlor cars and the cancellation of the surcharge applicable on tickets good in sleeping or parlor cars, the Central Passenger, the New England Passenger and the Trunk Line associations have discontinued granting special fares for conventions. The Southeastern, the Southwestern, the Transcontinental and the Western passenger associations do not grant so-called convention fares, but in their respective territories, as well as in the territories of the Eastern and Western Canadian passenger associations, there are effective daily round trip fares. No credentials will be necessary when purchasing tickets.

Members of the American Medical Association in the territories of the Central Passenger, the New England Passenger and the Trunk Line associations who expect to attend the annual session in Atlantic City may purchase one way tickets, but it would be more advantageous for them to avail themselves of summer or all-year excursion fares, as the excursion fares are less than the combination of the one way fares going and returning. The summer and all-year excursion tickets are good going and returning by the same route only and are not good going by one route and returning by another. Summer excursion tickets to Atlantic City require validation by signature at the ticket office in Atlantic City, which may be cared for at the time the ticket agent in Atlantic City is consulted regarding sleeping or parlor car accommodations for the return trip, but all-year excursion tickets do not require validation.

SURF BATHERS AT ATLANTIC CITY

Members in the territories of the Southeastern, Southwestern, Transcontinental and Western passenger associations, when purchasing their tickets to Atlantic City, are requested to consult their local ticket agents concerning daily round trip fares, which are based on a convention fare to and from the boundaries of those parts of the territories of the eastern passenger associations through which the members will have to travel to reach Atlantic City plus the fares in effect in territories of the eastern passenger associations. Such round trip

tickets may be purchased in the territory of the Southeastern Passenger Association with return limits of fifteen days and six months; in the territory of the Southwestern Passenger Association with return limits of fifteen days, thirty days and six months, and in the territories of the Transcontinental and Western passenger associations with return limit of thirty days.

SURF RIDERS—CONVENTION HALL AND HOTELS IN THE BACKGROUND

If a return limit longer than thirty days and up to six months is desired in the territories of the Transcontinental and Western passenger associations, through tickets are on sale daily on the basis of fare and two thirds of the one way first class fare for the round trip.

Summer excursion fares will also be in effect from the territories of the Transcontinental and Western passenger associations to Atlantic City, information concerning which should be secured from the local ticket agent.

No credentials will be necessary when purchasing tickets. If, however, summer excursion tickets to Atlantic City are purchased, they must be validated at the ticket office in Atlantic City.

Air Travel

Airline service from all parts of the United States to Atlantic City is available to those who desire to utilize this speedy form of transportation to the annual session.

There is practically no city in the United States more distant from Atlantic City than twenty hours by plane or a combination of air-rail service, and there is overnight service from points as distant as 2,000 miles.

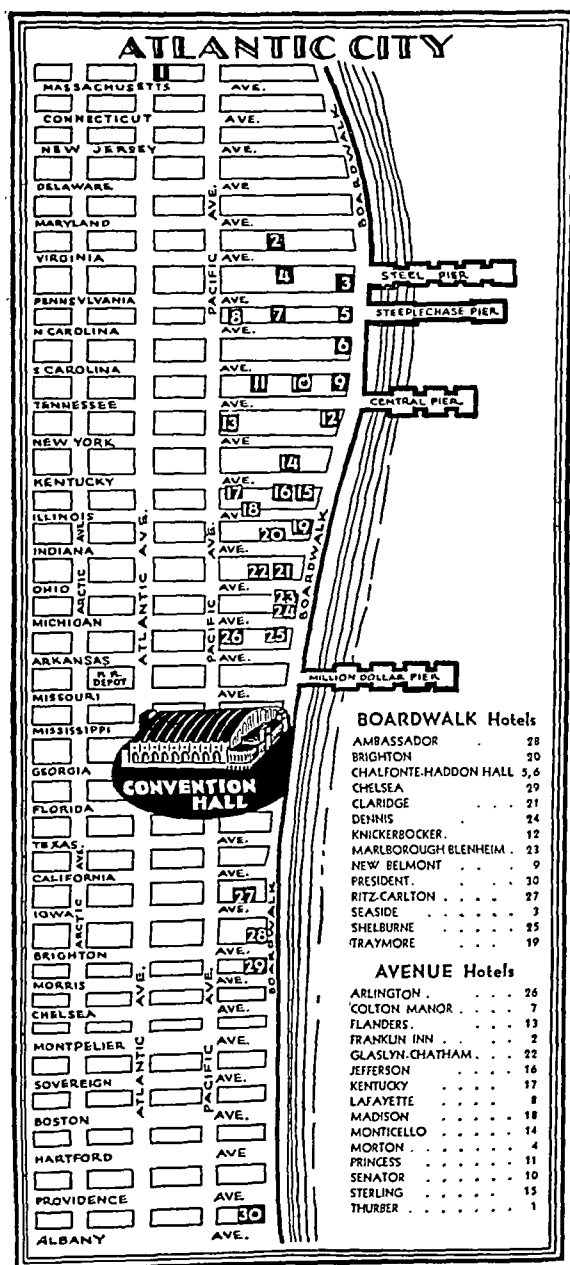

United Air Lines and Transcontinental and Western Air, Inc., have announced new lower fares. Special circle tour arrangements will permit air travelers to visit both Philadelphia and New York without payment of extra fare, and there will be "doctors' specials" from several important cities.

For particulars, ask your local representative of United Air Lines or Transcontinental and Western Air, Inc. Representatives of air lines will be in Atlantic City for the handling of return reservations and general air travel information.

REGISTRATION

The Bureau of Registration will be located in the Convention Hall, Boardwalk between Mississippi and Georgia avenues. Members of the Subcommittee on Registration of the Local Committee on Arrangements will be on hand to assist those who desire to register. A branch postoffice in charge of government postoffice officials will be available for visitors, and an information bureau will be operated in connection with the Bureau of Registration.

MAP OF ATLANTIC CITY AND
KEY TO MAP

Who May Register

Only Fellows, Affiliate, Associate and Honorary Fellows, and Invited Guests may register and take part in the work of the sections. Fellows of the Scientific Assembly are those who have, on the prescribed form, applied for Fellowship, subscribed to THE JOURNAL, and paid their Fellowship dues for the current year. The annual Fellowship dues provide a subscription to THE JOURNAL for one year. Fellowship cards are sent to all Fellows after payment of annual dues, and these cards

should be presented at the registration window. Any who have not received cards for 1937 should secure them at once by writing to the American Medical Association, 535 North Dearborn Street, Chicago.

Members in Good Standing Eligible to Apply for Fellowship in the Association

Members in good standing in component county medical societies are members of constituent state associations and of the American Medical Association. All members in good standing may apply for Fellowship in the Scientific Assembly and are urged to qualify as Fellows before leaving home in order that pocket cards may be secured and brought to Atlantic City so that registration can be more easily and more promptly effected.

Application forms may be had on request.

Those subscribers to THE JOURNAL who have not received pocket cards for 1937 should write to the American Medical Association for application blanks and information as to further requirements.

Register Early

Fellows living in Atlantic City, as well as all other Fellows who are in Atlantic City on Monday and Tuesday, should register as early as possible. The names of those who register will appear in the issue of the *Daily Bulletin* appearing the next day, and this will enable visiting physicians to find friends if they have registered.

Suggestions That Will Facilitate Registration

Fellows should fill out completely the spaces on both sections of the front of the *white* registration card, which will be found on the tables in front of the Registration Bureau.

Physicians who desire to qualify as Fellows should fill out completely the spaces on both sections of the front of the *blue* registration card, and sign the application on the back. These cards will be found on the tables.

Entries on the registration cards should be written plainly, or printed, as the cards are given to the printer to use as "copy" for the *Daily Bulletin*, published on Tuesday, Wednesday, Thursday and Friday of the week of the session.

Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out *white* registration card, together with their pocket cards, at one of the windows marked "Registration by Pocket Card." There the clerk will compare the two cards, stamp the pocket card and return it, and supply the Fellow with a badge, a copy of the official program and other printed matter of interest to those attending the annual session.

As previously stated, it will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than May 20. Any applications that are received later than May 20 will be given prompt attention, but the Fellowship pocket card may not reach the applicant in time for him to register at the Atlantic City session.

It will be possible for members of the organization to qualify as Fellows at Atlantic City. In order to do this, applicants for Fellowship will be required to fill out both sections of the front of the *blue* registration card and to sign the formal application that is printed on the reverse side of the card. It is suggested that those members who apply for Fellowship at Atlantic City bring with them their state membership cards for 1937. The state membership card should be presented along with the filled in *blue* registration card at the window in the booth marked "Applicants for Fellowship and Invited Guests."

As already stated, registration can be effected more easily and more promptly if members will qualify as Fellows before leaving home.

Registration for General Officers and Delegates at the Ambassador Hotel

General Officers of the American Medical Association and members of the House of Delegates may register for the

Scientific Assembly at a booth near the Renaissance Room of the Ambassador Hotel. This arrangement is made for the convenience of the members of the House of Delegates, which will convene on Monday morning at 10 o'clock in the Renaissance Room of the Ambassador Hotel. Delegates are requested to register for the Scientific Assembly before presenting cre-

dentials to the Reference Committee on Credentials of the House of Delegates. Registration of delegates for the Scientific Assembly will begin at 8 o'clock, Monday morning, June 7, and delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

TALKING MOTION PICTURE ON SYPHILIS

It is expected that a talking motion picture on syphilis now being produced under the joint auspices of the American Medical Association and the United States Public Health Service will be ready for showing at the Atlantic City session. If the picture is ready, as expected, it will be shown immediately

after the Symposium on Syphilis in the General Scientific Meetings Tuesday afternoon, June 8, and immediately after the completion of the program of the Section on Surgery, General and Abdominal, on the afternoons of Wednesday and Thursday, June 9 and 10.

ATLANTIC CITY HOTELS

A list of Atlantic City hotels is presented for the benefit of those who expect to attend the annual session of the American Medical Association, June 7-11. Dr. William Edgar Darnall is chairman of the Subcommittee on Hotels of the Local Com-

mittee on Arrangements and may be addressed at 16 Central Pier, Atlantic City, N. J. The advertising announcement and coupon for reservations appear on advertising page 115 of this issue.

THE ATLANTIC CITY SESSION

MEETING PLACES

HOUSE OF DELEGATES: Renaissance Room of the Ambassador Hotel, Boardwalk at Brighton Avenue.

OPENING GENERAL MEETING: Ballroom, Second Floor, Convention Hall.

GENERAL SCIENTIFIC MEETINGS: Ballroom, Second Floor, and Room E, First Floor, Convention Hall.

SECTIONS OF SCIENTIFIC ASSEMBLY
PRACTICE OF MEDICINE: Room E, First Floor, Convention Hall.

SURGERY, GENERAL AND ABDOMINAL: Ballroom, Second Floor, Convention Hall.

OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY: Ballroom, Second Floor, Convention Hall.

OPHTHALMOLOGY: Room B, First Floor, Convention Hall.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY: Room B, First Floor, Convention Hall.

PEDIATRICS: Room E, First Floor, Convention Hall.

PHARMACOLOGY AND THERAPEUTICS: Committee Room 13, Third Floor, Convention Hall.

PATHOLOGY AND PHYSIOLOGY: Committee Room 1, Floor, Convention Hall.

NERVOUS AND MENTAL DISEASES: Committee Room 2, Third Floor, Convention Hall.

DERMATOLOGY AND SYPHILOLOGY: Room A, First Floor, Convention Hall.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH: Room C, First Floor, Convention Hall.

UROLOGY: Room A, First Floor, Convention Hall.

ORTHOPEDIC SURGERY: Committee Room 12, Third Floor, Convention Hall.

GASTRO-ENTEROLOGY AND PROCTOLOGY: Room C, First Floor, Convention Hall.

RADIOLOGY: Room D, First Floor, Convention Hall.

GENERAL HEADQUARTERS, SCIENTIFIC EXHIBIT, REGISTRATION BUREAU, TECHNICAL EXHIBITS, INFORMATION BUREAU AND BRANCH POSTOFFICE: Convention Hall.

The Convention Hall is located on the Boardwalk between Mississippi and Georgia avenues.

LOCAL COMMITTEE ON ARRANGEMENTS

WILLIAM J. CARRINGTON, Chairman

HAROLD STERN DAVIDSON, Secretary

JOSEPH C. MARSHALL, Treasurer

Subcommittee on Sections and Section Work: Clarence L. Andrews, Chairman.

Practice of Medicine: David Ward Scanlan, Hilton S. Read, John S. Irvin.

Surgery, General and Abdominal: James H. Mason III, Uzzell, George A. Poland.

Obstetrics, Gynecology and Abdominal Surgery: Edward F. Ophthalmology: Halvor L. Harley, Albert Pilkington.

Laryngology, Otology and Rhinology: C. Coulter Charlton, S. Eugene Dalton.

Pediatrics: Walter B. Stewart, E. Harrison Nickman.

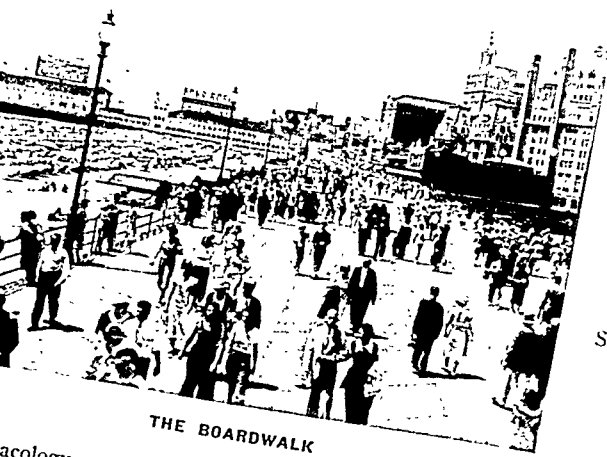

Preventive and Industrial Medicine and Public Health: Samuel L. Salasin, Robert M. Grier.

Urology: Charles H. deT. Shivers, Stanley M. McGeehan.

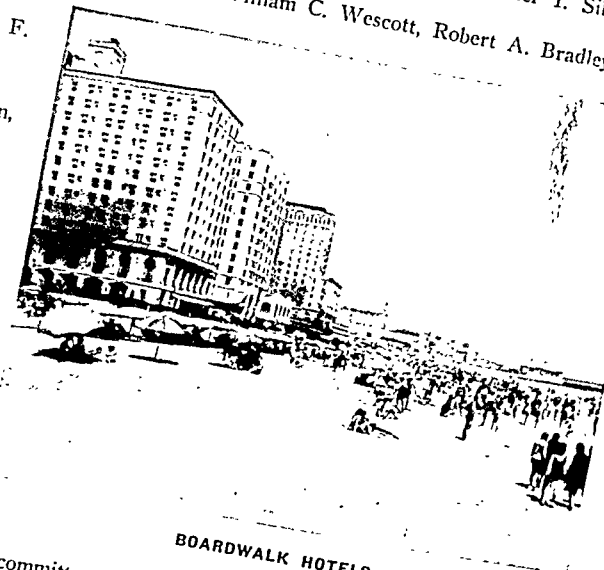

Orthopedic Surgery: Harry Subin, Edward Z. Holt.

Gastro-Enterology and Proctology: Homer I. Silvers, M. Browne Holoman.

Radiology: William C. Wescott, Robert A. Bradley.

THE BOARDWALK

BOARDWALK HOTELS

acology and Therapeutics: Lawrence A. Wilson, L. Walker.

ogy and Physiology: Charles Hyman, Isaac Shenfeld.

and Mental Diseases: William Cole Davis, William

ogy and Syphilology: William O. Roop, Abraham

er.

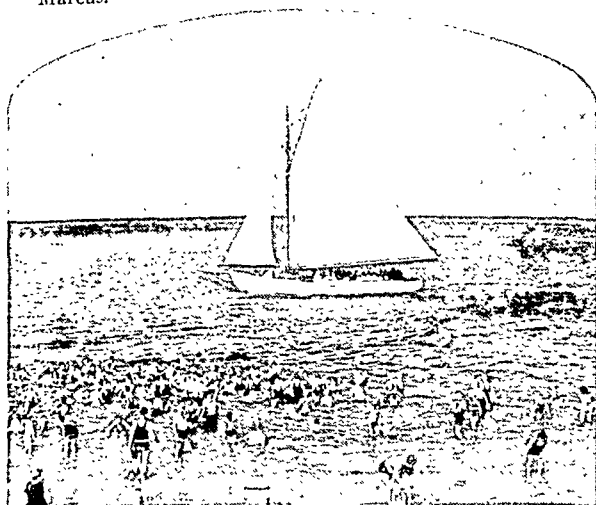

Subcommittee on Registration: Clyde M. Fish, Chairman; Theophilus H. Boysen, W. Paxson Chalfonte, Elisha C. Chew, Joseph P. Cleary, Samuel M. Diskan, William A. Donnelly, Edward H. Dyer, Arthur E. Ewens, William W. Fox, Clarence Garrabrant, Benjamin L. Gordon, Carl Gordon, Gerald L. Infield, Milton S. Ireland, John Joseph Jacobson, Stanley L. Lucas, Leo Kahn, Leland S. Madden, Peter H. Marvel, Daniel C. Reyner, Allan Rieck, Charles Schwinn, A. Burton Shimer, Ernest L. Shore, Charles D. Sinkinson, Carl Surran, Samuel L. Winn.

Subcommittee on Technical Exhibits: Isaac E. Leonard, Chairman; S. Worth Clark, Louis Mackler.

Subcommittee on Scientific Exhibit: Robert A. Kilduffe, Chairman; William W. Hersohn, Clarence B. Whims.

Subcommittee on Hotels: William E. Darnall, Chairman; Maurice H. Axilrod, Kenneth P. Henderson.

Subcommittee on Printing and Badges: Louis Feinstein, Chairman; Albert E. Forsythe, Harry S. Hoffman, Joseph H. Marcus.

SET SAIL FOR ATLANTIC CITY

Subcommittee on Information: Edward Guion, Chairman; Roland T. de Hellebranth, Henry C. James, James C. Mevay, D. J. M. Miller, Louis Rosenberg, Sidney Rosen-

blatt, George C. Schwarzkopf, Samuel Stern, Samuel Stalberg, Alexander Stevenson, Samuel E. Weiner, Raymond A. Williams.

Subcommittee on Publicity: Samuel Barbash, Chairman; Filbert R. Corson, Bernard Crane, Herman Kline, W. L. Eckert.

ATLANTIC CITY EXPOSITION, 1935

GOLF TOURNAMENT

The American Medical Golfing Association will hold its twenty-third annual tournament at the beautiful Seaview Country Club on Monday, June 7.

SEVENTY TROPHIES AND PRIZES

Thirty-six holes of golf will be played in competition for the seventy trophies and prizes in the nine events. Trophies will be awarded for the Association Championship, thirty-six holes gross, the Will Walter Trophy; the Association Handicap Championship, thirty-six holes net, the Detroit Trophy; the Championship Flight, First Gross, thirty-six holes, the St. Louis Trophy; the Championship Flight, First Net, thirty-six holes, the President's Trophy; the Eighteen Hole Championship, the Golden State Trophy; the Eighteen Hole Handicap Championship, the Ben Thomas Trophy; the Maturity Event, limited to Fellows over 60 years of age, the Minneapolis Trophy; the Oldguard Championship, limited to competition of past presidents, the Wendell Phillips Trophy, and the Kickers Handicap, the Wisconsin Trophy. Other events and prizes will be announced at the first tee.

FELLOWS IN EVERY STATE OF THE UNION

W. Albert Cook of Tulsa, Okla., is president and E. S. Edgerton of Wichita, Kan., and Clarence Capell of Kansas City, Mo., are vice presidents of the American Medical Golfing Association, which was organized in 1915 by Will Walter, Wendell Phillips and Gene Lewis, and now totals 1,300 members representing every state in the Union. The living past presidents include Thomas Hubbard of Toledo, Fred Bailey of St. Louis, Edward Martin of Media, Pa., Robert Moss of La Grange,

K. Nicoll of Chicago, Charles Lukens of Toledo, Ohio, and M. M. Cullom of Nashville, Tenn.

WALT P. CONAWAY AGAIN HEADS ATLANTIC CITY
GOLF COMMITTEE

The Atlantic City Committee is under the general chairmanship of Walt P. Conaway, 1723 Pacific Avenue, who so ably managed the 1925 tournament at Seaview, and the 1935 com-

SEAVIEW COUNTRY CLUB. HERE THE A. M. G. A. WILL
HOLD ITS 1937 TOURNAMENT

ATLANTIC CITY COUNTRY CLUB, NORTHFIELD

Texas, Charlton Wallace of New York, Will Walter of Evanston, Ill., and Charlottesville, Va., James Eaves of Oakland, Calif., Chester Brown of Danbury, Conn., Samuel Childs of Denver, W. D. Sheldon of Rochester, Minn., Walter Schaller of San Francisco, Edwin Zabriskie of New York, Frank A. Kelly of Detroit, John Welsh Croskey of Philadelphia, Homer

petition at the Northfield Club. He will be assisted by I. R. Beir, John Pennington, Karl Scott, Alfred Westney and R. R. White.

APPLICATION FOR MEMBERSHIP

All male Fellows of the American Medical Association are eligible and cordially invited to become members of the A. M. G. A. Write the Executive Secretary, Bill Burns, 2020 Olds Tower, Lansing, Mich., for an application blank. Participants in the A. M. G. A. tournament are required to furnish their home club handicap, signed by the club secretary. No handicap over 30 is allowed, except in the Kickers (Blind Bogey). Only active members of A. M. G. A. may compete for prizes. No trophy is awarded a Fellow who is absent from the annual dinner.

SEAVIEW A MAGNIFICENT COURSE

The twenty-third tournament of the American Medical Golfing Association at Seaview promises to be a pleasant affair. The club is one of the most elaborate in the country. The A. M. G. A. officers anticipate that some two hundred medical golfers from all parts of the United States will play in Atlantic City on June 7.

THE SCIENTIFIC EXHIBIT, ATLANTIC CITY MEETING

THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings—The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order that will be followed in the Official Program, nor is the list complete. The Official Program will be similar to the programs issued in previous years and will contain the final program of each section with abstracts of the papers, as well as lists of committees, program of the Opening General Meeting, list of entertainments, map of Atlantic City, and other information. To prevent misunderstandings and protect the interest of advertisers, it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each Fellow on registration.

SECTION ON PRACTICE OF MEDICINE

MEETS IN ROOM E, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

Chairman—JOHN H. MUSSEY, New Orleans.
Vice Chairman—RALPH H. MAJOR, Kansas City, Mo.
Secretary—JOSEPH T. WEARN, Cleveland.
Executive Committee—GEORGE R. MINOT, Boston; WILLIAM J. KERR, San Francisco; JOHN H. MUSSEY, New Orleans.

Wednesday, June 9—9 a. m.

Coronary Disease in Youth (Lantern Demonstration).
R. EARLE GLENDY and PAUL D. WHITE, Boston.
Discussion to be opened by H. M. MARVIN, New Haven, Conn., and W. D. STROUD, Philadelphia.
The Treatment of Acute Left Ventricular Failure (Lantern Demonstration). FRED M. SMITH, Iowa City.
Discussion to be opened by N. C. GILBERT, Chicago, and F. A. WILLIUS, Rochester, Minn.
The Frank Billings Lecture: The Cause of Pleural Shock. Air Embolism or Pleural Reflex (Lantern Demonstration). JOSEPH A. CAPPS, Chicago.
The Nature of Pregnancy Toxemias (Lantern Demonstration). JOHN P. PETERS, New Haven, Conn.
Pregnancy and Hypertension (Lantern Demonstration). J. EDWIN WOOD JR. and HAROLD G. NIX, University, Va.
Discussion on papers of DR. PETERS and DRs. WOOD and NIX to be opened by JOSEPH M. HAYMAN JR., Cleveland, and SONIA WEISS, Boston.
The Use of Sulfanilamide in the Treatment of Beta-Hemolytic Streptococcus Infections (Lantern Demonstration). PERRIN H. LONG and ELEANOR A. BLISS, Baltimore.
Discussion to be opened by CHESTER S. KEEFER, Boston, and FRANCIS F. SCHWENKER, Baltimore.

Thursday, June 10—9 a. m.

Studies with Human Influenza Virus During the Influenza Epidemic of 1936-1937 (Lantern Demonstration). THOMAS FRANCIS JR., New York.
Discussion to be opened by FRANCIS G. BLAKE, New Haven, Conn.
Chairman's Address: The Future of Internal Medicine. JOHN H. MUSSEY, New Orleans.
Newer Developments in Functional Heart Tests. GUSTAV NYLIN, Stockholm, Sweden.
Parasitism of the Tubercle Bacillus (Lantern Demonstration). WILLIAM CHARLES WHITE, Washington, D. C.
The Lasting Cure of Early Pulmonary Tuberculosis (Lantern Demonstration). J. BURNS AMBERSON, New York.
Problems in the Diagnosis and Management of Latent, Suspected and Early Clinical Tuberculosis. H. W. HETHERINGTON, Philadelphia.
Discussion on papers of DRs. WHITE, AMBERSON and HETHERINGTON to be opened by ESMOND R. LONG, Philadelphia; J. WOODS PRICE, Saranac Lake, N. Y.; BRUCE H. DOUGLAS, Detroit, and CHARLES H. COCKE, Asheville, N. C.

Friday, June 11—9 a. m.

Election of Officers

Prolonged Recumbency as a Contributory Cause of Death in Elderly Persons (Lantern Demonstration). L. B. LAPLACE and J. T. NICHOLSON, Philadelphia.
Discussion to be opened by ROBERT WILSON, Charleston, S. C., and CLARENCE L. ANDREWS, Atlantic City, N. J.
Refractory Anemia: Its Diagnosis and Treatment (Lantern Demonstration). C. P. RHOADS, New York.
Discussion to be opened by GEORGE R. MINOT, Boston, and RANDOLPH WEST, New York.
Gout (Lantern Demonstration). JOHN H. TALBOTT, Boston.
Discussion to be opened by WILLIAM S. LADD, New York, and P. S. HENCH, Rochester, Minn.
Hyperparathyroidism Simulating Paget's Disease (Lantern Demonstration). ALEXANDER B. GUTMAN and W. BARCLAY PARSONS, New York.
Discussion to be opened by WALTER BAUER, Boston.
Pulmonary Embolism (Lantern Demonstration). A. R. BARNES, Rochester, Minn.
Discussion to be opened by WILLIAM J. KERR, San Francisco; O. H. PERRY PEPPER, Philadelphia, and DAVID WARD SCANLAN, Atlantic City, N. J.
Night Blindness as a Criterion of Vitamin A Deficiency (Lantern Demonstration). HAROLD J. JEGHERS, Boston.
Discussion to be opened by M. A. BLANKENHORN, Cincinnati, and JOHN B. YOUNG, Nashville, Tenn.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

MEETS IN BALLROOM, SECOND FLOOR, CONVENTION HALL

OFFICERS OF SECTION

Chairman—ROBERT S. DINSMORE, Cleveland.
Vice Chairman—ALTON OCHSNER, New Orleans.
Secretary—HENRY W. CAVE, New York.
Executive Committee—JOHN L. YATES, Milwaukee; HOWARD M. CLUTE, Boston; ROBERT S. DINSMORE, Cleveland.

Wednesday, June 9—2 p. m.

The Treatment of Craniocerebral Trauma (Lantern Demonstration). CHALMERS H. MOORE, Birmingham, Ala.
Discussion to be opened by WALTER E. DANDY, Baltimore, and R. GLEN SPURLING, Louisville, Ky.
Blood Chemistry Studies in Thyroid Crisis (Lantern Demonstration). WALTER G. MADDOCK, FREDERICK A. COLLIER and SVEND PEDERSEN, Ann Arbor, Mich.
Discussion to be opened by GEORGE CRILE JR., New York, and JOHN PAUL NORTH, Philadelphia.
Chairman's Address: Prevention of Morbidity in Thyroid Surgery. ROBERT S. DINSMORE, Cleveland.
Present Day Status of Surgery of the Heart and Pericardium. ARTHUR M. SHIPLEY, Baltimore.
Discussion to be opened by CLAUDE S. BECK, Cleveland, and ISAAC ALEXANDER BIGGER, Richmond, Va.
Congenital Hypertrophic Pyloric Stenosis in Infancy (Lantern Demonstration). EDWARD J. DONOVAN, New York.
Discussion to be opened by WILLIAM E. LADD, Boston, and ALFRED JEROME BROWN, Omaha.
Partial Gastrectomy for Gastric and Duodenal Ulcer (Lantern Demonstration). SAMUEL F. MARSHALL and EVERETT D. KIEFER, Boston.
Discussion to be opened by EVERETT D. KIEFER, Boston, and JOHN G. MATEER, Detroit.

Thursday, June 10—2 p. m.

Recent Advances in Anesthesia (Lantern Demonstration). JOHN S. LUNDY, Rochester, Minn.
Discussion to be opened by HENRY S. RUTH, Philadelphia, and RALPH M. TOVELL, Hartford, Conn.
Technical Procedures in Use of Modern Anesthetics (Lantern Demonstration). PAUL M. WOOD, New York.
Discussion to be opened by EMERY A. ROVENSTINE, New York, and H. BOYD STEWART, Tulsa, Okla.
Partial Cholecystectomy in Acute Suppurative Cholecystitis (Lantern and Motion Picture Demonstration). WILLIAM L. ESTES JR., Bethlehem, Pa.
Discussion to be opened by WILLIAM D. HAGGARD, Nashville, Tenn., and DONALD GUTHRIE, Sayre, Pa.

Instrumental Dilation of the Ampulla of Vater: Experimental and Clinical Observations (Lantern Demonstration).

ROBERT ZOLLINGER, CHARLES D. BRANCH and ORVILLE T. BAILEY, Boston.

Discussion to be opened by EDMUND ANDREWS, Chicago.

Postoperative Care of Bile Tract Surgery (Lantern Demonstration).

ROBERT LEE PAYNE, Norfolk, Va.

Discussion to be opened by EDWIN P. LEHMAN, University, Va., and HAROLD L. FOSS, Danville, Pa.

Diagnostic and Therapeutic Problems Presented by Lesions of Right Lower Quadrant (Lantern Demonstration).

OTTO CARL PICKHARDT and HENRY AARON RAFSKY, New York.

Discussion to be opened by ERNEST H. GAITHER, Baltimore.

Friday, June 11—2 p. m.

Election of Officers

Purpura Haemorrhagica, with Special Reference to Its Course and Treatment (Lantern Demonstration).

EDWARD M. HANRAHAN JR., MAXWELL M. WINTROBE and CAROLINE B. THOMAS, Baltimore.

Discussion to be opened by ALLEN O. WHIPPLE, New York, and GEORGE R. MINOT, Boston.

Present Views Regarding Irradiation as an Aid to Surgery in Cancer of the Breast (Lantern Demonstration).

WILLIAM CRAWFORD WHITE, New York.

Discussion to be opened by FRANK E. ADAIR, New York, and ERNEST M. DALAND, Boston.

The Prevention of Postoperative Adhesions About Nerve and Tendon Sutures (Lantern Demonstration).

LOYAL DAVIS and LEON J. ARIES, Chicago.

Discussion to be opened by HERBERT L. JOHNSON, Boston, and FRANCIS C. GRANT, Philadelphia.

Rectal Symptoms from the General Surgeon's Point of View.

HARVEY B. STONE, Baltimore.

Discussion to be opened by CURTICE ROSSER, Dallas, Texas, and FRANK C. YEOMANS, New York.

Right Colectomy for Malignant Disease: A Discussion of the Mortality Associated with Various Operative Procedures (Lantern Demonstration).

ARTHUR W. ALLEN, Boston.

Discussion to be opened by FRED W. RANKIN, Lexington, Ky., and FREDERICK A. COLLIER, Ann Arbor, Mich.

Further Experience with a New Tendoplastic Amputation Through the Femur at the Knee (Lantern and Motion Picture Demonstration).

C. LATIMER CALLANDER, San Francisco.

Discussion to be opened by JOSEPH S. MCGUINNESS, San Francisco, and PHILIP DUNCAN WILSON, New York.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

MEETS IN BALLROOM, SECOND FLOOR, CONVENTION HALL

OFFICERS OF SECTION

Chairman—M. PIERCE RUCKER, Richmond, Va.

Vice Chairman—BUFORD G. HAMILTON, Kansas City, Mo.

Secretary—EVERETT D. PLASS, Iowa City.

Executive Committee—JAMES R. MCCORD, Atlanta, Ga.; LYLE G. MCNEILE, Los Angeles; M. PIERCE RUCKER, Richmond, Va.

Wednesday, June 9—9 a. m.

An Evaluation of Common Lesions of the Cervix (Lantern Demonstration).

NORMAN F. MILLER and RUSSELL L. MALCOLM, Ann Arbor, Mich.

The Diagonal Conjugate versus X-Ray Pelvimetry (Lantern Demonstration).

A. LOUIS DIPPEL, Baltimore.

Normal Expectancy in the Extremely Obese Pregnant Woman (Lantern Demonstration).

HARVEY B. MATTHEWS and MAURICE G. DER BRUCKE, Brooklyn.

The Treatment of Repeated Abortion and Repeated Antenatal and Postnatal Deaths (Lantern Demonstration).

K. DE SNOO, Utrecht, Holland.

Thursday, June 10—9 a. m.

SYMPOSIUM ON THE CLINICAL USE OF ENDOCRINE PRODUCTS

Oligomenorrhea and Amenorrhea: Causation and Treatment (Lantern Demonstration).

ROBERT T. FRANK, MORRIS A. GOLDBERGER and U. J. SALMON, New York.

The Management of Menorrhagia and Metrorrhagia by Endocrine Products (Lantern Demonstration).

JOHN C. BURCH, Nashville, Tenn.

The Endocrines in Relation to Sterility and Abortion (Lantern Demonstration).

JENNINGS C. LITZENBERG, Minneapolis.

Endocrine Treatment of Vaginitis of Children and Women After the Menopause (Lantern Demonstration).

ROBERT M. LEWIS, New Haven, Conn.

The Endocrine Treatment of Menopausal Phenomena (Lantern Demonstration).

JEAN PAUL PRATT, Detroit.

Chairman's Address: The Treatment of Eclampsia.

M. PIERCE RUCKER, Richmond, Va.

Friday, June 11—9 a. m.

Election of Officers

Evaluation by Controlled Series of Vaginal Trichomoniasis Therapies (Lantern Demonstration).

H. CLOSE HESSELTINE, Chicago.

Further Studies of the Clinical Use of the Concentrated (Hemolytic) Streptococcus Antitoxic Serum in Puerperal Fever (Lantern Demonstration).

ABRAHAM F. LASH, Chicago.

Results of Radiation Therapy for Carcinoma of the Uterus at the Woman's Hospital (Lantern Demonstration).

GEORGE GRAY WARD and NELSON B. SACKETT, New York.

Breech Deliveries: A Comparative Study of Local and General Anesthesia.

HARRIS J. TIMMERMAN, Chicago.

Hydatidiform Mole and Chorionepithelioma (Lantern Demonstration).

NICHOLAS M. ALTER, Jersey City, N. J.

Further Observations on the Use of the Anterior Pituitary-like Principle as an Intradermal Pregnancy Test (Lantern Demonstration).

JOHN HUBERMAN, H. H. ISRAELOFF and BEN HYMOWITZ, Newark, N. J.

SECTION ON OPHTHALMOLOGY

MEETS IN ROOM B, FIRST FLOOR, CONVENTION HALL

Chairman—WILLIAM L. BENEDICT, Rochester, Minn.

Vice Chairman—EMORY HILL, Richmond, Va.

Secretary—PARKER HEATH, Detroit.

Executive Committee—ARTHUR J. BEDELL, Albany, N. Y.; JOHN GREEN, St. Louis; WILLIAM L. BENEDICT, Rochester, Minn.

Wednesday, June 9—2 p. m.

Chairman's Address (Lantern Demonstration).

WILLIAM L. BENEDICT, Rochester, Minn.

On Ophthalmic Education.

WALTER R. PARKER, Detroit.

The Visual Disturbances of Trachoma (Lantern Demonstration).

HARRY S. GRADLE, Chicago.

Discussion to be opened by HANS BARKAN, San Francisco, and JOHN GREEN, St. Louis.

An Unclassified Type of Optic Neuritis (Lantern Demonstration).

GRADY CLAY and J. M. BAIRD, Atlanta, Ga.

Discussion to be opened by E. L. GOAR, Houston, Texas.

Syphilis in Relation to the Prevention of Blindness (Lantern Demonstration).

CONRAD BERENS, New York.

Discussion to be opened by E. V. L. BROWN, Chicago.

Tryparsamide Therapy of Neurosyphilis and Optic Nerve Atrophy (Lantern Demonstration).

LEO L. MAYER, Chicago.

Discussion to be opened by FREDERICK C. CORDES, San Francisco, and WALTER I. LILLIE, Philadelphia.

Ocular Disturbances in Lesions of the Mesencephalic Central Gray Matter (Lantern Demonstration).

NORMAN P. SCALA, Washington, D. C., and ERNEST A. SPIEGEL, Philadelphia.

Discussion to be opened by CLIFFORD B. WALKER, Los Angeles.

Thursday, June 10—2 p. m.

The Near Reaction of the Pupil in the Dark: A Quantitative Study (Lantern Demonstration).

F. HERBERT HAESSLER, Milwaukee.

Discussion to be opened by FRANCIS H. ADLER, Philadelphia.

The Autonomic Nervous System and Accommodation (Lantern Demonstration).

DAVID G. COGAN, Boston.

Discussion to be opened by WILLIAM H. LUEDDL, St. Louis, and ALFRED BIELSCHOWSKY, Hanover, N. H.

Late Results of Cataract Extraction.

EDWARD JACKSON, Denver.
Discussion to be opened by ALLEN GREENWOOD, Boston,
and EDWARD C. ELLETT, Memphis, Tenn.

Surgical Corrections for Enophthalmos and Exophthalmos (Lantern and Motion Picture Demonstration).

ROBERT E. MORAN, Washington, D. C.
Discussion to be opened by ARNOLD KNAPP, New York.

Demonstration Session

Friday, June 11—2 p. m.

Executive Session

Election of Officers

Formation of Drusen of the Lamina Vitrea (Lantern Demonstration). BENJAMIN RONES, Washington, D. C.

Discussion to be opened by FREDERICK H. VERHOEFF, Boston, and ARTHUR J. BEDELL, Albany, N. Y.

Blepharoptosis (Lantern Demonstration).

EDMUND B. SPAETH, Philadelphia.
Discussion to be opened by FERRIS SMITH, Grand Rapids, Mich., and DANIEL B. KIRBY, New York.

Tobacco Amblyopia:

I. Treatment of Tobacco Amblyopia with Vasodilators (Lantern Demonstration).

WALTER F. DUGGAN, New York.
Discussion to be opened by LAWRENCE T. POST, St. Louis.

II. The Importance of Diet in the Etiology and Treatment of Tobacco Alcohol Amblyopia (Lantern Demonstration). FRANK D. CARROLL, New York.

Discussion to be opened by ARTHUR M. YUDKIN, New Haven, Conn.

The Dominant Eye: Its Clinical Significance.

WALTER H. FINK, Minneapolis.
Discussion to be opened by DERRICK T. VAIL JR., Cincinnati.

SECTION ON LARYNGOLOGY, OTOTOLOGY
AND RHINOLOGY

MEETS IN ROOM B, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

Chairman—ROBERT F. RIDPATH, Philadelphia.

Vice Chairman—LEROY A. SCHALL, Boston.

Secretary—GORDON B. NEW, Rochester, Minn.

Executive Committee—JOHN J. SHEA, Memphis, Tenn.; RALPH A. FENTON, Portland, Ore.; ROBERT F. RIDPATH, Philadelphia.

Wednesday, June 9—9 a. m.

Osteomyelitis of the Jaws (Lantern Demonstration).

THOMAS E. CARMODY, Denver.
Discussion to be opened by C. STEWART NASH, Rochester, N. Y.; V. H. KAZANJIAN, Boston, and ROBERT H. IVY, Philadelphia.

Fracture of the Skull Involving the Paranasal Sinuses and Mastoid (Lantern Demonstration).

CLAUDE C. COLEMAN, Richmond, Va.
Discussion to be opened by FRANCIS C. GRANT, Philadelphia; HARRY E. MOCK, Chicago, and WELLS P. EAGLETON, Newark, N. J.

The Management of Pulsion Esophageal Diverticulum Based on an Operative Experience with Seventy Cases and a Follow-Up Study of Forty-Five Cases (Lantern Demonstration). FRANK H. LAHEY, Boston.

Discussion to be opened by STUART W. HARRINGTON, Rochester, Minn., and THOMAS A. SHALLOW and W. WAYNE BABCOCK, Philadelphia.

Measuring the Sensation of Loudness: A New Approach to the Physiology of Hearing and the Functional and Differential Diagnostic Tests (Lantern Demonstration).

EDMUND PRINCE FOWLER, New York.
Discussion to be opened by WALTER HUGHSON, Abington, Pa.; DOUGLAS MACFARLAN, Philadelphia; HORACE NEWHART, Minneapolis, and FREDERICK T. HILL, Waterville, Maine.

Prophylactic Vaccination Against Intracranial Complications Following Pneumococcus Type III Mastoiditis (Lantern Demonstration). JOSEPH L. GOLDMAN, New York.

Discussion to be opened by RUSSELL L. CECIL, New York; W. E. GROVE, Milwaukee, and ISIDORE FRIESNER, New York.

Thursday, June 10—9 a. m.

Chairman's Address: A Plea for a Better Understanding Between the Laryngologist and the Vocal Teacher.

ROBERT F. RIDPATH, Philadelphia.

Otology in Relation to General Medicine (Lantern Demonstration). BURT R. SHURLY, Detroit.

Discussion to be opened by FRANK R. SPENCER, Boulder, Colo.; W. P. WHERRY, Omaha, and CLAUDE P. BROWN, Philadelphia.

Critique of the Present Treatment of Conducting Mechanism Deafness (Lantern Demonstration).

ISIDORE FRIESNER, New York.

Discussion to be opened by S. J. CROWE, Baltimore; EDWARD H. CAMPBELL, Philadelphia, and JOHN RANDOLPH PAGE, New York.

A Comment on the Treatment of Chronic Purulent Otitis Media. ROBIN HARRIS, Jackson, Miss.

Discussion to be opened by SAMUEL J. KOPETZKY, New York, and BENJAMIN H. SHUSTER, Philadelphia.

Treatment of Lateral Sinus Thrombosis with Ligation of the Internal Jugular Vein (Lantern Demonstration).

MATTHEW S. ERSNER and DAVID MYERS, Philadelphia.

Discussion to be opened by H. MARSHALL TAYLOR, Jacksonville, Fla., and MARVIN FISHER JONES, New York.

The Medical Treatment of Blood Stream Infection with Special Reference to Immunized Blood Transfusions (Lantern Demonstration). E. G. GILL, Roanoke, Va.

Discussion to be opened by JOHN A. KOLMER and JAMES A. BABBITT, Philadelphia, and EARL LE ROY WOON, Newark, N. J.

Friday, June 11—9 a. m.

Election of Officers

Congenital Occlusion of the Posterior Choana: Operative Treatment (Lantern Demonstration).

C. M. ANDERSON, Rochester, Minn.

Discussion to be opened by J. P. SCHAEFFER and HARRY P. SCHENCK, Philadelphia; R. C. GROVE, New York, and H. I. LILLIE, Rochester, Minn.

Foreign Bodies in the Food and Air Passages: Their Early and Late Effects (Lantern Demonstration).

ROYAL REYNOLDS, Washington, D. C.

Discussion to be opened by CHEVALIER JACKSON, Philadelphia; HERMAN J. MOERSCH, Rochester, Minn., and W. LIKELY SIMPSON, Memphis, Tenn.

Tumors of the True Vocal Cords: Malignant and Benign (Lantern Demonstration).

GABRIEL TUCKER, Philadelphia.

Discussion to be opened by HENRY B. ORTON, Newark, N. J.; CHARLES J. IMPERATORI, New York, and GORDON B. NEW, Rochester, Minn.

Exophthalmos as a Complication of Sinus Malignancy (Lantern Demonstration). LEROY A. SCHALL, Boston.

Discussion to be opened by ALGERNON B. REESE, New York; KARL M. HOUSER, Philadelphia, and JOSEPH C. BECK, Chicago.

Triple Primary Carcinoma in Otolaryngology (Lantern Demonstration). JOSHUA C. DROOKER, Boston.

Discussion to be opened by FRANK W. KONZELMANN and LOUIS H. CLERF, Philadelphia, and LEROY A. SCHALL, Boston.

SECTION ON PEDIATRICS

MEETS IN ROOM E, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

Chairman—RALPH M. TYSON, Philadelphia.

Vice Chairman—ALDRICH C. CROWE, Ocean City, N. J.

Secretary—ALBERT D. KAISER, Rochester, N. Y.

Executive Committee—A. GRAEME MITCHELL, Cincinnati; HORTON R. CASPARIS, Nashville, Tenn.; RALPH M. TYSON, Philadelphia.

Wednesday, June 9—2 p. m.

Chairman's Address: Certain Significant Aspects of Childhood Tuberculosis. RALPH M. TYSON, Philadelphia.

Clinical Radiology in Pediatrics (Lantern Demonstration). WILLIAM E. CHAMBERLAIN, Philadelphia.

The Dietetic Treatment of Eczema in Early Infancy. LEWIS WEBB HALL, Boston.

Discussion to be opened by RALPH BOWEN, Oklahoma City, and T. WOOD CLARKE, Utica, N. Y.

- The Early Detection and Treatment of Hearing Defects in Children. HORACE NEWHART, Minneapolis.
Discussion to be opened by J. VICTOR GREENBAUM, Cincinnati, and AUSTIN A. HAYDEN, Chicago.
- The Treatment of Nephrosis in the Young Child (Lantern Demonstration). FRED W. SCHLUTZ and J. L. COLLIER, Chicago.
Discussion to be opened by SAMUEL W. CLAUSEN, Rochester, N. Y.
- The Teaching of Body Mechanics in Pediatric Practice (Lantern and Motion Picture Demonstration). CLIFFORD D. SWEET, Oakland, Calif.
Discussion to be opened by ROBERT B. OSGOOD, Boston, and ALFRED J. SCOTT, Los Angeles.

Thursday, June 10—2 p. m.

- Municipal Control of Whooping Cough (Lantern Demonstration). LOUIS W. SAUER, Evanston, Ill.
Discussion to be opened by LEROY D. FOTHERGILL, Boston, and CHARLES GILMORE KERLEY, New York.
- A Comparison Between the Use of Diphtheria Precipitated Toxoid and the Fluid Toxoid as a Preventive (Lantern Demonstration). WILLIAM H. PARK, New York.
Discussion to be opened by M. Bernard Brahdly, Mount Vernon, N. Y.
- Immunization with the Active Virus of Human Influenza: A Two Year Study (Lantern Demonstration). JOSEPH STOKES JR., Philadelphia.
Discussion to be opened by THOMAS FRANCIS JR., New York.
- Active and Passive Immunity in Poliomyelitis. JOHN A. TOOMEY, Cleveland.
Discussion to be opened by JOSEPH YAMPOLSKY, Atlanta, Ga., and JOHN FITCH LONDON, New York.
- The Prevention and Modification of Measles (Lantern Demonstration). CHARLES F. MCKHANN, Boston.
Discussion to be opened by SAMUEL KARELITZ New York, and A. CLEMENT SILVERMAN, Syracuse, N. Y.
- Isolation Technic: Its History and Results (Lantern Demonstration). PHILIP M. STIMSON, New York.
Discussion to be opened by HAVEN EMERSON, New York, and HARRY H. DONNALLY, Washington, D. C.

Friday, June 11—2 p. m.

Election of Officers

- Abnormalities of Fat Metabolism in Childhood (Lantern Demonstration). L. EMMETT HOLT JR., Baltimore.
Discussion to be opened by WALTER R. BLOOR, Rochester, N. Y., and S. J. THANNHAUSER, Boston.
- Experiences with Communicable Disease Control in Private Practice (Lantern Demonstration). C. A. STEWART and E. S. PLATOU, Minneapolis.
Discussion to be opened by LEE FORREST HILL, Des Moines, Iowa, and HENRY T. PRICE, Pittsburgh.
- The Allergic Crippled Child. MILTON B. COHEN, Cleveland.
Discussion to be opened by J. ALEXANDER CLARKE JR., Philadelphia, and W. AMBROSE MCGEE, Richmond, Va.
- Epidemic Diarrhea of the New-Born (Lantern Demonstration). JOHN L. RICE, SAMUEL FRANT and HAROLD ABRAMSON, New York.
Discussion to be opened by WILBURT C. DAVISON, Durham, N. C., and JOHN AIKMAN, Rochester, N. Y.
- Wood Tick Aparalysis in Children (Motion Picture Demonstration). E. J. BARNETT and C. L. LYON, Spokane, Wash.
Discussion to be opened by JAY I. DURAND, Seattle, and R. E. DYER, Washington, D. C.
- The Diagnosis of Heart Disease in Children (Lantern Demonstration). MAY G. WILSON, New York.
Discussion to be opened by WILLIAM D. STROUD, Philadelphia, and HYMAN GREEN, Boston.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

MEETS IN COMMITTEE ROOM 13, THIRD FLOOR,
CONVENTION HALL

OFFICERS OF SECTION

- Chairman—N. C. GILBERT, Chicago.
Vice Chairman—RUSSELL L. HADEN, Cleveland.
Secretary—IRVING S. WRIGHT, New York.
Executive Committee—CARL H. GREENE, New York; CHAUNCEY D. LEAKE, San Francisco; N. C. GILBERT, Chicago.

Wednesday, June 9—2 p. m.

- Effects of Induced Oxygen Want in Patients with Cardiac Pain (Lantern Demonstration). ROBERT L. LEVY, ALVAN L. BARACH and HOWARD G. BRUENN, New York.
Discussion to be opened by H. J. STEWART, New York.
- The Treatment of Coronary Sclerosis by Producing a New Blood Supply to the Heart (Lantern Demonstration). HAROLD FEIL and CLAUDE S. BECK, Cleveland.
Discussion to be opened by WALLACE M. YATER, Washington, D. C.
- Clinical Studies of Respiration: Observations on the Action of Theophylline with Ethylene Diamine on the Intrathecal and Venous Pressures and on the Bronchi as a Possible Mechanism for Its Beneficial Effect on Cheyne-Stokes Breathing, Dyspnea and Paroxysmal Dyspnea (Lantern Demonstration). JAMES A. GREENE, W. D. PAUL and A. E. FELLER, Iowa City.
Discussion to be opened by G. K. FENN, Chicago, and T. R. HARRISON, Nashville, Tenn.
- Observations on the Effects of Vitamin B (B₁) Therapy on the Polyneuritis of Alcohol Addicts. ROBERT S. GOODHART and NORMAN JOLLIFFE, New York.
Discussion to be opened by GEORGE R. COWGILL, New Haven, Conn.; MARTIN G. VORHAUS, New York, and TOM D. SPIES, Cincinnati.
- The Treatment of Undulant Fever with Intravenous Typhoid Vaccine (Lantern Demonstration). C. E. ERVIN and HENRY F. HUNT, Danville, Pa.
Discussion to be opened by FRANK J. SLADEN, Detroit, and WALTER M. SIMPSON, Dayton, Ohio.
- Pathologic Physiology of the Common Bile Duct and Its Relation to Biliary Colic (Lantern Demonstration). WALTMAN WALTERS, Rochester, Minn.
Discussion to be opened by A. C. IVY, Chicago; ROBERT L. PAYNE, Norfolk, Va., and R. RUSSELL BEST, Omaha.

Thursday, June 10—2 p. m.

- Chairman's Address. N. C. GILBERT, Chicago.
- Observations on Acacia Therapy in Nephrosis (Lantern Demonstration). EUGENE M. LANDIS, Philadelphia.
Discussion to be opened by A. F. HARTMANN, St. Louis, and NORMAN M. KEITH, Rochester, Minn.
- Human Autonomic Pharmacology (Lantern Demonstration). ABRAHAM MYERSON, Boston.
- Clinical Observations on the Effects of Benzadrine Sulfate (Lantern Demonstration). D. L. WILBUR, A. R. MACLEAN and E. V. ALLEN, Rochester, Minn.
Discussion on papers of DR. MYERSON and DRS. WILBUR, MACLEAN and ALLEN to be opened by A. J. CARLSON, Chicago, and WALTER B. CANNON, Boston.
- The Effect of Diuresis by Mercurials on the Clinical Course of Congestive Heart Failure (Lantern Demonstration). LAURENCE E. HINES, Chicago.
Discussion to be opened by ARTHUR C. DEGRAFF, New York, and JAMES G. CARR and CHAUNCEY C. MAHER, Chicago.
- Antipneumococcus Rabbit Serum as a Therapeutic Agent in Lobar Pneumonia. F. L. HORSFALL JR., KENNETH GOODNER, COLIN M. MACLEOD and ALBERT H. HARRIS 2D, New York.
Discussion to be opened by J. G. M. BULLOWA and RUSSELL L. CECIL, New York.

Friday, June 11—2 p. m.

Election of Officers

- The Prolongation of Insulin Action (Lantern Demonstration). D. A. SCOTT, A. M. FISHER and C. H. BEST, Toronto, Canada.
- Protamine Zinc Insulin: Clinical Application (Lantern Demonstration). HERMAN O. MOSENTHAL, New York.
- Protamine Insulin: Clinical Experience (Lantern Demonstration). EDWIN J. KEPPLER, Rochester, Minn.
- What Protamine Insulin Might Accomplish for the Diabetic Problem in the United States. ELLIOTT P. JOSLIN, Boston.
Discussion to be opened by C. N. H. LONG, New Haven, Conn.; WALTER R. CAMPBELL, Toronto, Canada, and CARL H. GREENE, New York.

**SECTION ON PATHOLOGY AND
PHYSIOLOGY**MEETS IN COMMITTEE ROOM 13, THIRD FLOOR,
CONVENTION HALL**OFFICERS OF SECTION**

Chairman—W. E. GARREY, Nashville, Tenn.

Vice Chairman—R. R. KRACKE, Atlanta, Ga.

Secretary—J. J. MOORE, Chicago.

Executive Committee—ELIAS P. LYON, Minneapolis; HENRY C. SWEANY, Chicago; W. E. GARREY, Nashville, Tenn.

Wednesday, June 9—9 a. m.Sarcoma Resulting from the Ingestion of a Crude, Ether-
Extracted Wheat Germ Oil (Lantern and Motion Picture
Demonstration).L. G. ROWNTREE, GEORGE M. DORRANCE and E. F.
CICCONI, Philadelphia.Krukenberg Tumors of the Ovary (Lantern Demonstration).

and R. GLEN SPURLING, Louisville, Ky.Vitamin Therapy of Muscular Dystrophy (Lantern and Motion
Picture Demonstration).DANIEL V. CONWILL, Halstead, Kan.
Discussion to be opened by B. LANDIS ELLIOTT, Kansas
City, Mo., and W. E. ASH, Council Bluffs, Iowa.

- A Clinical Evaluation of Quinine in Myotonia and of Prostigmin in Myasthenia (Motion Picture Demonstration).
FOSTER KENNEDY and ALEXANDER WOLF, New York.
- A New Test for Diagnosis of Certain Headaches: The Cephalalgogram (Lantern Demonstration).
TEMPLE S. FAY, Philadelphia.
Discussion to be opened by WILDER PENFIELD, Montreal, Canada, and JAMES W. WATTS, Washington, D. C.

Friday, June 11—2 p. m.

Election of Officers

- Chairman's Address: Neurology; Past and Present (Lantern Demonstration). HENRY R. VIETS, Boston.
- Hypoglycemia: Neurologic and Neuropathologic Study (Lantern Demonstration).
FREDERICK P. MOERSCH and JAMES W. KERNOHAN, Rochester, Minn.
Discussion to be opened by FRANK N. ALLAN and STANLEY COBB, Boston.

DEMENTIA PRAECOX

- The Status of Research in Dementia Praecox in 1936 (Lantern Demonstration). NOLAN D. C. LEWIS, New York.
- Hypoglycemic Insulin Treatment: A Brief Review.
JOSEPH WORTIS and KARL M. BOWMAN, New York.
- Experiences in the Insulin-Hypoglycemia Treatment of Cases of Schizophrenia of Long Duration.
D. EWEN CAMERON, Worcester, Mass., and R. G. HOSKINS, Boston.
- Hypoglycemia Treatment of Schizophrenia with Particular Reference to the Qualitative Study of Remissions: A Preliminary Report.
CHARLES A. RYMER, JOHN D. BENJAMIN and FRANKLIN G. EBAUGH, Denver.
Discussion on papers of DR. LEWIS, DR. WORTIS and BOWMAN, DR. CAMERON and HOSKINS and DR. RYMER, BENJAMIN and EBAUGH to be opened by RICHARD H. YOUNG, Omaha; LLOYD H. ZIEGLER, Albany, N. Y., and FRANK N. ALLAN, Boston.
- Electro-Encephalography in the Psychoses (Lantern Demonstration).
FREDERICK LEMERE, Medical Lake, Wash.
Discussion to be opened by HALLOWELL DAVIS, Boston, and RALPH W. GERARD, Chicago.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

MEETS IN ROOM A, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

- Chairman—PAUL A. O'LEARY, Rochester, Minn.
- Vice Chairman—CHARLES C. DENNIE, Kansas City, Mo.
- Secretary—BEDFORD SHELMIER, Dallas, Texas.
- Executive Committee—JEFFREY C. MICHAEL,* Houston, Texas;
HARRY R. FOERSTER, Milwaukee; PAUL A. O'LEARY, Rochester, Minn.

*Deceased.

Wednesday, June 9—2 p. m.

- Chairman's Address: Present Day Status of Treatment of Neurosyphilis. PAUL A. O'LEARY, Rochester, Minn.
- Hemiatrophia Faciei Progressiva.
ELMORE B. TAUBER and LEON GOLDMAN, Cincinnati.
Discussion to be opened by EARL D. OSBORNE, Buffalo.
- Pyogenic Relapse and Light Sensitiveness in Certain Dermatoses: Influence of an Intercurrent Infection Factor.
JOHN H. STOKES and J. LAMAR CALLAWAY, Philadelphia.
Discussion to be opened by MARION B. SULZBERGER, New York.
- Relationship of Pityrosporum Ovale to Seborrheic Dermatitis: Further Investigations (Lantern Demonstration).
ROY L. KILE and M. F. ENGMAN SR., St. Louis.
Discussion to be opened by RICHARD S. WEISS, St. Louis.
- Torch Oil Dermatitis: Its Relation to Interdigital Epidermomycosis (Lantern Demonstration).
ADOLPH G. KAMMER, East Chicago, Ind.
Discussion to be opened by HARRY R. FOERSTER, Milwaukee.
- Stomatitis Venenata: Report of an Unusual Case of Mucous Membrane and Cutaneous Sensitivity to Oil of Anise (Lantern Demonstration).
ADOLPH B. LOVEMAN, Louisville, Ky.
Discussion to be opened by JOHN GODWIN DOWNING, Boston.

- Results of Leukopenic Index Tests in Atopic Dermatitis (Lantern Demonstration). ELMER M. RUSTEN, Minneapolis.
Discussion to be opened by THEODORE L. SQUIER, Milwaukee.

Thursday, June 10—2 p. m.

- The Cardiovascular Syphilitic Patient.
LEWIS B. ROBINSON, New York.
Discussion to be opened by HARRY L. BAER, Pittsburgh.
- The Problem of Seroresistant Syphilis (So-Called Wassermann Fastness) (Lantern Demonstration).
JOSEPH EARLE MOORE and PAUL PADGET, Baltimore.
Discussion to be opened by FRANCIS E. SENEAR, Chicago.
- The Clinical Evaluation of Iodobismitol in the Treatment of Syphilis.
CHARLES W. BARNETT and GEORGE V. KULCHAR, San Francisco.
Discussion to be opened by M. T. VAN STUDDIFORD, New Orleans.
- The Intradermal Chancroid Bacillary Antigen Skin Test as a Further Aid in the Differential Diagnosis of Venereal Diseases.
ROBERT B. GREENBLATT and EVERETT S. SANDERSON, Augusta, Ga.
Discussion to be opened by HAROLD N. COLE, Cleveland.
- The Absorption of Drugs and Poisons Through Skin and Mucous Membranes (Lantern Demonstration).
DAVID I. MACHT, Baltimore.
Discussion to be opened by ISAAC R. PELS, Baltimore.
- Lupus Erythematosus: Its Increased Incidence in Philadelphia, with Studies Pertaining to the Disease.
JOHN B. LUDY and EDWARD F. CORSON, Philadelphia.
Discussion to be opened by C. GUY LANE, Boston.
- Ammonium Succinimido-Aurate: A Gold Compound of Low Toxicity (Lantern Demonstration).
M. E. OBERMAYER and S. WILLIAM BECKER, Chicago.
Discussion to be opened by CARROLL S. WRIGHT, Philadelphia.

Friday, June 11—2 p. m.

Election of Officers

- Naevus Epithelioma Cyliindromatosis (Lantern Demonstration).
GEORGE W. BINKLEY, Cleveland.
Discussion to be opened by FRED D. WEIDMAN, Philadelphia.
- Relapsing Febrile Nodular Nonsuppurative Panniculitis (Lantern Demonstration).
RICHARD J. BAILEY, Rochester, Minn.
Discussion to be opened by E. W. NETHERTON, Cleveland.
- Melanin Production as Induced by Aniline Dye (Indelible Ink) (Lantern Demonstration). HERMAN SHARLIT, New York.
Discussion to be opened by SAMUEL M. PECK, New York.
- The Intra-Oral Use of Superficial X-Rays: A Report of the Use of the Chaoul Tube (Lantern Demonstration).
LESTER HOLLANDER and JOSEPH M. SHELTON, Pittsburgh.
Discussion to be opened by FREDERICK M. JACOB, Pittsburgh.
- Epidermal Carcinoma as a Biologic Phenomenon: The Mutation Theory (Lantern Demonstration).
RICHARD L. SUTTON JR., Kansas City, Mo.
Discussion to be opened by EVERETT C. FOX, Dallas, Texas.
- Discussion of an Original Method of Treatment for Warts.
JACK G. HUTTON, Denver.
Discussion to be opened by WILLIAM HOWARD HAILEY, Atlanta, Ga.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

MEETS IN ROOM C, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

- Chairman—L. D. BRISTOL, New York.
- Vice Chairman—J. F. BREDECK, St. Louis.
- Acting Secretary—IRL C. RIGGIN, Richmond, Va.
- Executive Committee—ROBERT H. RILEY, Baltimore; R. R. SAYERS, Washington, D. C.; L. D. BRISTOL, New York.

Wednesday, June 9—9 a. m.

- Volatile Solvents as a Problem in Industrial Medicine (Lantern Demonstration).
W. J. MCCONNELL, New York.
Discussion to be opened by HENRY FIELD SMYTH, Philadelphia.

Filtrable Viruses in Infection of Human Upper Respiratory Tract. YALE KNEELAND JR., New York.
Discussion to be opened by RUSSELL L. CECIL, New York.

Chairman's Address: Next Steps in the Organization and Administration of Preventive and Industrial Medicine and Public Health. L. D. BRISTOL, New York.

Social Security and the Doctor. E. A. MEYERDING, St. Paul.
Discussion to be opened by HOLMAN TAYLOR, Fort Worth, Texas.

Endemic Typhus in Native Rodents (Lantern Demonstration). R. E. DYER, Washington, D. C.
Discussion to be opened by JOHN J. PHAIR, Baltimore.

Thursday, June 10—9 a. m.

A Study of Silicosis. PHILIP B. MATZ, Washington, D. C.
Discussion to be opened by R. R. SAYERS, Washington, D. C.

Correlation on the Positive Tuberculin Reaction and the Shape of the Chest (Lantern Demonstration).

S. A. WEISMAN, Minneapolis.

The Relative Value of Schilling Differential Counts, the Sedimentation Rates and Lymphocyte-Monocyte Ratios in Tuberculosis of Childhood (Lantern Demonstration).

W. AMBROSE MCGEE, Richmond, Va.

Discussion to be opened by FRANK B. STAFFORD, Charlottesville, Va.

Intensive Case Finding Work on Tuberculosis (Lantern Demonstration). HENRY F. VAUGHAN, Detroit.

Chronic Mercurialism in the Hatters' Fur-Cutting Industry (Lantern Demonstration).

PAUL A. NEAL and R. R. JONES, Washington, D. C.
Discussion to be opened by D. CHESTER BROWN, Danbury, Conn.

Friday, June 11—9 a. m.

Election of Officers

Active Immunization of Human Beings Against Tetanus by Means of Tetanus Toxoid (Lantern Demonstration).

HERMAN GOLD, Chester, Pa.

Discussion to be opened by LOUIS TUFT, Philadelphia.

The Performance of Serodiagnostic Tests for Syphilis in State Laboratories (Lantern Demonstration).

WALTER M. SIMPSON, Dayton, Ohio.

Discussion to be opened by FREDERICK H. LAMB, Davenport, Iowa.

The Campaign Against Syphilis in New York City. WALTER CLARKE, New York.

Discussion to be opened by CHARLES C. DENNIE, Kansas City, Mo.

Industrial Preventive Medicine: A Plan for Control of Occupational Diseases. C. D. SELBY, Detroit.

The Management of the Cardiac Patient in Industry (Lantern Demonstration).

R. B. CRAIN and MORRIS E. MISSAL, Rochester, N. Y.

Personal Experiences with Gas Bacillus Infection. D. A. BENNETT, Canton, Ill.

SECTION ON UROLOGY

MEETS IN ROOM A, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

Chairman—HENRY W. E. WALTHER, New Orleans
Vice Chairman—NELSE F. OCKERBLAD, Kansas City, Mo.
Secretary—WILLIAM P. HERBST, Washington, D. C.
Executive Committee—STANLEY R. WOODRUFF, Jersey City, N. J.; JOHN H. MORRISSEY, New York; HENRY W. E. WALTHER, New Orleans.

Wednesday, June 9—9 a. m.

SYMPOSIUM ON PEDIATRIC UROLOGY

Pyelitis of Infancy: The Late Results in Untreated Cases (Lantern Demonstration).

LAWRENCE R. WHARTON and HARRIET G. GUILD, Baltimore.

Tumors of the Genito-Urinary Tract in Children (Lantern Demonstration). MEREDITH F. CAMPBELL, New York.

Nonobstructive Upper Urinary Tract Dilatations in Children (Lantern Demonstration).

ALEXANDER B. HEPLER, Seattle.

Discussion on papers of DRs. WHARTON and GUILD, DR. CAMPBELL and DR. HEPLER to be opened by N. G. ALCOCK, Iowa City; P. M. BUTTERFIELD, New York, and VINCENT VERMOUTEN, Johannesburg, South Africa.

A New Operation for Hypospadias (Lantern Demonstration). O. S. LOWSLEY, New York.

Discussion to be opened by J. EASTMAN SHEEHAN, New York.

The Origin and Growth of Renal Calculi (Lantern Demonstration). ALEXANDER RANDALL, Philadelphia.

Silent Renal Calculi (Lantern Demonstration). JAMES T. PRIESTLEY and WILLIAM F. BRAASCH, Rochester, Minn.

Signs of Vitamin A Deficiency in the Eye Correlated with Urinary Lithiasis (Lantern Demonstration). WILLIAM J. EZICKSON and JACOB B. FELDMAN, Philadelphia.

Discussion on papers of DR. RANDALL, DRs. PRIESTLEY and BRAASCH and DRs. EZICKSON and FELDMAN to be opened by J. D. BARNEY, Boston; ROBERT H. HERBST, Chicago; LEON HERMAN, Philadelphia; LINWOOD D. KEYSER, Roanoke, Va.; JOHN H. MORRISSEY, New York; MILEY B. WESSON, San Francisco, and STANLEY R. WOODRUFF, Jersey City, N. J.

Thursday, June 10—9 a. m.

The Effect of Neosphenamine in Urinary Infections (Lantern Demonstration). JOHN M. PACE, Dallas, Texas.

Chairman's Address: Urinary Antisepsis.

HENRY W. E. WALTHER, New Orleans.

Discussion on papers of DRs. PACE and WALTHER to be opened by ANSON L. CLARK, Oklahoma City, and MONROE E. GREENBERGER, New York.

Changes in the Urinary Tract Associated with Lesions of the Genital Tract in Women (Lantern Demonstration). HERMAN L. KRETSCHMER and A. E. KANTER, Chicago.

Discussion to be opened by ROSEMARY SHOEMAKER, Rochester, Minn., and WILLIAM E. STEVENS, San Francisco.

SYMPOSIUM ON GENITO-URINARY MALIGNANCY

The Treatment of Primary Carcinoma of the Male Urethra (Lantern Demonstration).

HENRY A. R. KREUTZMANN, San Francisco.

Recent Advances in the Diagnosis and Treatment of Tumor of the Testis.

FRANK HINMAN, San Francisco, and T. O. POWELL, Los Angeles.

Malignant Growths of the Bladder (Lantern Demonstration). O. A. NELSON, Seattle.

Renal Neoplasms: A Review of Cases and Indications for Treatment (Lantern Demonstration).

THEODORE R. FETTER, Philadelphia.

The Treatment of Urinary Tract Malignancy with Super-voltage Roentgen Irradiation.

ARBOR D. MUNGER, Lincoln, Neb.

Discussion on papers of DR. KREUTZMANN, DRs. HINMAN and POWELL, DR. NELSON, DR. FETTER and DR. MUNGER to be opened by H. C. BUMPUS JR., Pasadena, Calif.; JAMES L. ESTES, Tampa, Fla.; Russell S. FERGUSON and Alfred F. Hocker, New York, and HUGH H. YOUNG, Baltimore.

Friday, June 11—9 a. m.

Election of Officers

Decapsulation and Nephrostomy in Anuria Due to Bichloride or Phenol Poisoning (Lantern Demonstration).

GEORGE R. LIVERMORE, Memphis, Tenn.

Discussion to be opened by NELSE F. OCKERBLAD, Kansas City, Mo.

Undergraduate Urologic Instruction (Lantern and Motion Picture Demonstration). ROGER W. BARNES, Los Angeles.

Discussion to be opened by GEORGE F. CAHILL, New York, and R. M. LE COMTE, Washington, D. C.

SYMPOSIUM ON GONOCOCCIC INFECTIONS

The Program of the Public Health Service in the More Effective Control of Gonorrhea.

R. A. VONDERLEHR, Washington, D. C.

- The Treatment of Gonococcic Infections with Sulfanilamide (Para-Aminobenzenesulfonamide) (Lantern Demonstration). J. A. C. COLSTON and JOHN E. DEES, Baltimore.
- The Significance of Variation in Morphology of the Gonococcus (Lantern Demonstration).

RUSSELL D. HERROLD, Chicago.

- An Evaluation of Laboratory Methods Used for the Diagnosis of Gonococcic Infections in the Male and Female (Lantern Demonstration).

CHARLES M. CARPENTER, Rochester, N. Y.

- Artificially Induced Fever in the Treatment of Gonococcic Infection in the Male.

W. W. SCOTT and S. L. WARREN, Rochester, N. Y.

- Color Motion Picture Demonstration of Laboratory Cultural Technic of the Gonococcus. H. C. HESSELTINE, Chicago.

Discussion on papers of DR. VONDERLEHR, DR. COLSTON and DEES, DR. HERROLD, DR. CARPENTER and DR. SCOTT and WARREN to be opened by WILLIAM BIERMAN, New York; HENRY B. GWYNN, Washington, D. C.; RALPH H. JENKINS, New Haven, Conn., and FREDERICK S. SCHOFIELD, Philadelphia.

SECTION ON ORTHOPEDIC SURGERY

MEETS IN COMMITTEE ROOM 12, THIRD FLOOR,

CONVENTION HALL

OFFICERS OF SECTION

- Chairman—FREMONT A. CHANDLER, Chicago.
Vice Chairman—JOHN DUNLOP, Pasadena, Calif.
Secretary—ROBERT V. FUNSTEN, Charlottesville, Va.
Executive Committee—ROBERT D. SCHROCK, Omaha; ARTHUR T. LEGG, Boston; FREMONT A. CHANDLER, Chicago.

Wednesday, June 9—9 a. m.

- Comparison of Treatments and Their Results in Fractures of the Shaft of the Femur (Lantern Demonstration).

E. L. ELIASON, Philadelphia.
Discussion to be opened by JOHN ALBERT KEY, St. Louis, and P. H. SCARDINO, Houston, Texas.

- End Result of Twenty-One Years of Spine Fusion for Tuberculosis.

W. H. VON LACKUM, New York.
Discussion to be opened by ARCHIBALD F. O'DONOGHUE, Sioux City, Iowa; Roland Hammond, Providence, R. I., and R. PLATO SCHWARTZ, Rochester, N. Y.

- The Etiology of Cartilaginous Exostoses and Giant Cell Tumors of the Bone (Lantern Demonstration).

J. DEWEY BISGARD, Omaha.
Discussion to be opened by L. D. SMITH, Milwaukee; MARION BECKETT HOWORTH, New York, and I. WILLIAM NACHLAS, Baltimore.

- The Dynamic Biologic Relativity of Nerve, Muscle and Bone Pressure During Growth and Maturity.

EBEN J. CAREY, Milwaukee.
Discussion to be opened by ARTHUR STEINDLER, Iowa City; EDWARD L. COMPERE, Chicago, and MANDELL SHIMBERG, Wadsworth, Kan.

- The Importance of Adequate Fracture Treatment in Rural Hospitals.

W. T. HAMMOND, Easton, Md.
Discussion to be opened by ROBERT WILKINSON JOHNSON JR., Baltimore; VOIGHT MOONEY, Pittsburgh, and Z. B. ADAMS, Boston.

- A Comparative Study of the Surgical and Nonoperative Method of Treating Bone and Joint Tuberculosis (Lantern Demonstration).

LEO MAYER, New York.
Discussion to be opened by JAMES TORRENCE RUGH, Philadelphia; BENJAMIN P. FARRELL, New York, and ALBERT L. BERSHON, Toledo, Ohio.

Thursday, June 10—9 a. m.

- Lesions of the Intervertebral Disks.

W. J. MIXTER, J. S. BARR and A. O. HAMPTON, Boston.
Discussion to be opened by GEORGE I. BAUMAN, Cleveland; SAMUEL J. LANG, Evanston, Ill., and C. FRED FERCIOT, Lincoln, Neb.

- The Neurologic Significance of Low Back Pain (Lantern Demonstration).

R. GLEN SPURLING and F. H. MAYFIELD, Louisville, Ky.
Discussion to be opened by G. E. HAGGART, Boston; CHARLES MURRAY GRATZ, New York, and E. S. GURDJIAN, Detroit.

- The Relation of Fascia Lata to Low Back Conditions.

FRANK R. OBER, Boston.
Discussion to be opened by ALAN DEF. SMITH, New York; MAX HARBIN, Cleveland, and EDWIN W. RYERSON, Chicago.

- Differential Diagnosis in Low Back Pain (Lantern Demonstration).

ARTHUR STEINDLER, Iowa City.
Discussion to be opened by JOHN C. WILSON, Los Angeles; WILLIAM BARNETT OWEN, Louisville, Ky., and A. R. SHANDS JR., DURHAM, N. C.

- Arthrodesis in Osteo-Arthritis of the Hip (Lantern and Motion Picture Demonstration).

R. WATSON JONES, Liverpool, England.

- The Treatment of Chronic Arthritis of the Foot (Lantern Demonstration).

JOHN G. KUHN, Boston.
Discussion to be opened by Robert B. Osgood, Boston; PAUL P. SWETT, Hartford, Conn., and Louis E. PAPURT, Cleveland.

Friday, June 11—9 a. m.

- Election of Officers

- Pathologic Fractures (Lantern Demonstration).

RALPH K. GHORMLEY, Rochester, Minn.

- The Occurrence of an Osseous Dyscrasia in Gastrectomized Puppies (Lantern Demonstration).

A. C. IVY and SMITH FREEMAN, Chicago.
Discussion to be opened by DANIEL H. LEVINTHAL, Chicago; WALTER G. STUCK, San Antonio, Texas, and PAUL W. LAPIDUS, New York.

- Malunited Colles' Fractures (Lantern and Motion Picture Demonstration).

WILLIS C. CAMPBELL, Memphis, Tenn.
Discussion to be opened by H. R. CONN, Akron, Ohio; FRANK D. DICKSON, Kansas City, Mo., and GEORGE E. BENNETT, Baltimore.

- Chairman's Address: Localized Overgrowth of the Extremities and Spine (Lantern Demonstration).

FREMONT A. CHANDLER, Chicago.

- Simplified Technic of On Lay Grafts for all Ununited Fractures in Acceptable Position (Lantern and Motion Picture Demonstration).

D. B. PHENISTER, Chicago.
Discussion to be opened by J. S. SPEED, Memphis, Tenn.; EARL D. MCBRIDE, Oklahoma City, and LEWIS CLARK WAGNER, New York.

- Fractures of the Os Calcis (Lantern Demonstration).

H. W. SPIERS, Los Angeles.
Discussion to be opened by RUDOLPH S. REICH, Cleveland; J. A. LINK, Springfield, Ohio, and WILLIAM B. CARRELL, Dallas, Texas.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN ROOM C, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

- Chairman—LOUIS A. BUIE, Rochester, Minn.
Vice Chairman—HENRY L. BOCKUS, Philadelphia.
Secretary—A. H. AARON, Buffalo.
Executive Committee—WALTER A. FANSLER, Minneapolis; ERNEST H. GAITHER, Baltimore; LOUIS A. BUIE, Rochester, Minn.

Wednesday, June 9—2 p. m.

- A Study of Peptic Ulcer from Necropsy Records (Lantern Demonstration).

SIDNEY ALEXANDER PORTIS and RICHARD HERMANN JAFFÉ, Chicago.

Discussion to be opened by JOHN L. KANTOR, New York; CLAYTON W. GREENE, Buffalo, and SARA M. JORDAN, Boston.

- The Influence of the Duodenum on the Functions of the Small Intestine (Lantern Demonstration).

THOMAS G. MILLER, Philadelphia; WILLIAM O. ABBOTT, Wynnewood, Pa., and WALTER G. KARR, Philadelphia.
Discussion to be opened by EUGENE P. PENNERGRASS and HARRY SHAY, Philadelphia.

- Acute Abdominal Catastrophes.

IRVIN ABELL, Louisville, Ky.
Discussion to be opened by FRANK H. LAHEY, Boston; ROBERT LEE PAYNE, Norfolk, Va., and HARVEY B. STONE, Baltimore.

Coccygodynia and Pain in the Superior Gluteal Region and Down the Back of the Leg: Observations on the Causation of Such Pain by Tonic Spasm of the Levator Ani, Coccygeus and Piriformis Muscles, and Its Relief by Massage of These Muscles (Lantern Demonstration).

GEORGE HENRY THIELE, Kansas City, Mo.

Discussion to be opened by FRANK D. DICKSON and FERNANDO I. WILSON, Kansas City, Mo.

Vesical Dysfunction Following Abdominoperineal Resection of Carcinoma of Rectum (Lantern and Motion Picture Demonstration).

MALCOLM ROBERT HILL and CYRIL BRIAN COURVILLE, Los Angeles.

Discussion to be opened by DUDLEY A. SMITH, San Francisco, and DESCUM C. MCKENNEY, Buffalo.

Mucosal Pattern Technic and Kymographic Records of the Esophagus and Stomach (Lantern Demonstration).

EDWARD HOLMAN SKINNER, Kansas City, Mo.

Discussion to be opened by WENDELL G. SCOTT, St. Louis, and LESTER LEVYN, Buffalo.

The Formation and Treatment of Experimental Peptic Ulcers Produced by Cinchophen (Lantern Demonstration).

JESSE LOUIS BOLLMAN, Rochester, Minn.

Discussion to be opened by GEORGE B. EUSTERMAN, Rochester, Minn., and LESTER R. DRAGSTEDT, Chicago.

Thursday, June 10—2 p. m.

Chairman's Address: The Value of Specialization in Medicine.

LOUIS A. BUIE, Rochester, Minn.

Management of Colostomy (Motion Picture Demonstration).

DUDLEY A. SMITH, San Francisco.

Discussion to be opened by THOMAS E. JONES, Cleveland, and ROLLIN R. BEST, Omaha.

Right-Sided Colitis: Life History and Treatment.

BURRILL BERNARD CROHN and ALBERT ASHTON BERG, New York.

Discussion to be opened by RICHARD B. CATTELL, Boston, and J. ARNOLD BARGEN, Rochester, Minn.

What Happens to Patients Who Have Diverticulosis and Diverticulitis of the Colon (Lantern Demonstration)?

PHILIP WALLING BROWN and D. M. MARCLEY, Rochester, Minn.

Discussion to be opened by HENRY L. BOCKUS, Philadelphia, and CHESTER M. JONES, Boston.

A New Method of Diagnosis in Bacillary Dysentery.

DANIEL NATHAN SILVERMAN, New Orleans.

Discussion to be opened by JOHN H. MUSSER, New Orleans, and JOSEPH FELSEN, New York.

Pancreatic Fistula (Lantern Demonstration).

JOHN MILTON MCCAUGHAN, St. Louis.

Discussion to be opened by HOWARD M. CLUTE, Boston, and WILLIAM T. COUGHLIN, St. Louis.

Gastric Motor Disturbances Following Laparotomy.

LOUIS EDWARD BARRON, New Haven, Conn., and GEORGE MORRIS CURTIS, Columbus, Ohio.

Discussion to be opened by A. F. R. ANDRESEN, Brooklyn, and STOCKTON KIMBALL, Buffalo.

Friday, June 11—2 p. m.

Election of Officers

Gastritis: Gastroscopic Studies (Lantern Demonstration).

ERNEST HOWARD GAITHER, Baltimore, and JAMES L. BORLAND, Jacksonville, Fla.

Discussion to be opened by THOMAS R. BROWN, Baltimore, and RUDOLF SCHINDLER, Chicago.

The Importance of Surgery in Hematemesis Accompanied with Pyloric Obstruction (Lantern and Motion Picture Demonstration).

ANTHONY BASSLER, New York.

Discussion to be opened by ALBERT JOSEPH SULLIVAN, New Haven, Conn.

The Mechanism of Production of Digestive Symptoms Associated with Urologic Disturbances (Lantern and Motion Picture Demonstration).

PAUL BROWN WELCH, Miami, Fla.

Discussion to be opened by CHARLES L. HARTSOCK, Cleveland, and CLARENCE G. BANDLER, New York.

Treatment of Operable Rectal and Anal Cancer in Poor Surgical Risks (Lantern Demonstration).

GEORGE ERNEST BINKLEY, New York.

Discussion to be opened by DOUGLAS QUICK, New York, and CLEMENT JOSEPH DE BERE, Chicago.

Low Grade Partial Small Intestinal Obstruction (Lantern Demonstration).

LAY MARTIN, Baltimore.

Discussion to be opened by OWEN H. WANGENSTEEN, Minneapolis, and JULIUS FRIEDENWALD, Baltimore.

Intracutaneous Response to Bowel Exudate Antigens from Ulcerative Colitis and Its Relation to Presence of Virus: Comparison with Frei Reaction and Its Etiologic Significance in Colitis (Lantern Demonstration).

MOSES PAULSON, Baltimore.

Discussion to be opened by IRVING GRAY, Brooklyn.

Chronic Cholecystitis versus Irritable Colon (Lantern Demonstration).

SAMUEL ALLEN WILKINSON JR., Boston.

Discussion to be opened by CARL H. GREENE, New York; CLARENCE F. G. BROWN, Chicago, and RUSSELL S. BOLES, Philadelphia.

SECTION ON RADIOLOGY

MEETS IN ROOM D, FIRST FLOOR, CONVENTION HALL

OFFICERS OF SECTION

Chairman—ROSS GOLDEN, New York.

Vice Chairman—B. R. KIRKLIN, Rochester, Minn.

Secretary—JOHN T. MURPHY, Toledo, Ohio.

Executive Committee—JOHN W. PIERSON, Baltimore; EDWARD L. JENKINSON, Chicago; ROSS GOLDEN, New York.

Wednesday, June 9—2 p. m.

A Pathologic Study of Seventy-Five Patients Injected with Thorium Dioxide Sol for the Purpose of Making Hepatosplenograms (Lantern Demonstration).

WALLACE M. YATER and EUGENE R. WHITMORE, Washington, D. C.

Some Clinical Applications of Roentgen Kymography (Lantern Demonstration).

SYDNEY E. JOHNSON, Louisville, Ky.

Chairman's Address: Comments on Pyloric Spasm and Gastritis (Lantern Demonstration).

ROSS GOLDEN, New York.

Regional Ileitis (Lantern Demonstration).

JOSEPH JELLIN, Los Angeles.

Roentgen Diagnosis of Contusions of the Kidney.

MAX RITVO and DAVID B. STEARNS, Boston.

Pathologic Conditions of the Spine: Painful Disturbances of the Intervertebral Foramina (Lantern Demonstration).

LEE A. HADLEY, Syracuse, N. Y.

Thursday, June 10—2 p. m.

Obstructive Emphysema and Atelectasis in Influenza: A New Approach (Lantern Demonstration).

WILLIAM SNOW and CHARLES S. B. CASSASA, New York.

The Roentgen Aspect of Sympathetic Neuroblastoma (Lantern Demonstration).

HOWARD P. DOUB, Detroit.

A Survey of the Undergraduate Teaching of Radiology in the Medical Schools of the United States (Lantern Demonstration).

CLAUDE MOORE, Washington, D. C.

Experiences in Teaching Radiology to Undergraduate Students.

EUGENE P. PENDERGRASS, Philadelphia.

Graduate Education and Training of Radiologists (Lantern Demonstration).

B. R. KIRKLIN, Rochester, Minn.

Bronchus Carcinoma (Lantern Demonstration).

WALTER L. MATTICK and EUGENE M. BURKE, Buffalo.

Friday, June 11—2 p. m.

Election of Officers

Roentgen Therapy of Acute Pneumonias.

EUGENE V. POWELL, Temple, Texas.

Cancer of the Thyroid (Lantern Demonstration).

HUGH F. HARE and NEIL SWINTON, Boston.

The Heavily Filtered Roentgen Treatment of Superficial Epitheliomas (Lantern Demonstration).

E. A. MERRITT and R. RHETT RATHBONE, Washington, D. C.

The Value of Supervoltage Roentgen Therapy (Lantern Demonstration).

TRAIAN LEUCUTIA, Detroit.

Russell H. Boggs Memorial Lecture: The Value of Preoperative and Postoperative Irradiation in Carcinoma of the Breast (Lantern Demonstration).

G. E. PFAHLER and JACOB H. VASTINE, Philadelphia.

Treatment of Mammary Cancer. U. V. PORTMANN, Cleveland.

Lung Changes After Radiation (Lantern Demonstration).

HARRIET CARSWELL MCINTOSH and SOPHIE SMITZ, New York.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit will occupy the north end of the main floor and the stage of the Atlantic City Auditorium. The same general arrangement of booths and decorations will be carried out as in former years. In addition to the groups of exhibits sponsored by the fifteen sections of the Scientific Assembly there will be a special program on pneumonia conducted under the auspices of the Section on Practice of Medicine, and motion picture programs put on by the Sections on Ophthalmology, on Nervous and Mental Diseases, on Orthopedic Surgery and on Obstetrics, Gynecology and Abdominal Surgery. In cooperation with the American Heart Association there will be an exhibit symposium on heart disease covering all phases of the subject. The Board of Trustees has made appropriations for two special exhibits on the subjects of fractures and anesthesia.

Admission to the Scientific Exhibit will be limited to individuals wearing Fellowship or other badges of the convention and to guests to whom special cards of admission have been issued. The public will not be admitted to the Scientific Exhibit.

Following are the representatives to the Scientific Exhibit from the various sections:

FRED M. SMITH, Iowa City, Section on Practice of Medicine.
LESTER R. WHITAKER, Boston, Section on Surgery, General and Abdominal.

H. CLOSE HESSELTINE, Chicago, Section on Obstetrics, Gynecology and Abdominal Surgery.

GEORGIANA DVORAK-THEOBALD, Oak Park, Ill., Section on Ophthalmology.

LOUIS J. I. BURNS, Philadelphia, Section on Laryngology, Otolaryngology and Rhinology.

F. THOMAS MITCHELL, Memphis, Tenn., Section on Pediatrics.

WALLACE M. YATER, Washington, Section on Pharmacology and Therapeutics.

F. W. KONZELMANN, Philadelphia, Section on Pathology and Physiology.

PETER BASSOE, Chicago, Section on Nervous and Mental Diseases.

C. W. FINNERUD, Chicago, Section on Dermatology and Syphilology.

PAUL A. DAVIS, Akron, Ohio, Section on Preventive and Industrial Medicine and Public Health.

R. S. FERGUSON, New York, Section on Urology.

JESSE T. NICHOLSON, Philadelphia, Section on Orthopedic Surgery.

J. A. BARGEN, Rochester, Minn., Section on Gastro-Enterology and Proctology.

E. E. DOWNS, Woodbury, N. J., Section on Radiology.

Special Exhibit on Anesthesia

The exhibit on anesthesia this year is intended to be the first of a series on the science and art of modern anesthesia. The 1937 exhibit will stress the fundamentals, with emphasis on physiology and pharmacology. The exhibit is presented under the auspices of a general committee composed of D. Chester Brown, chairman, Danbury, Conn., Frank H. Lahey, Boston, and Paul Nicholas Leech, Chicago, assisted by members of the Associated Anesthetists of the United States and Canada, the American Society of Anesthetists, and the American Society of Regional Anesthesia.

In addition to continuous demonstrations by a competent corps of demonstrators there will be talks on anesthesia, both morning and afternoon, each day throughout the week in an area adjoining the exhibits. A pamphlet has been prepared for distribution.

Special Exhibit on Fractures

The exhibit on fractures is continued again this year along somewhat the same lines as last year. The special exhibit committee appointed by the Committee on Scientific Exhibit of the Board of Trustees is composed of the following:

Frank D. Dickson, Kansas City, Mo.

Walter Estell Lee, Philadelphia.

Kellogg Speed, chairman, Chicago.

There will be an advisory committee as follows:

ISIDORE COHN,
New Orleans.

H. EARLE CONWELL,
Fairfield, Ala.

FREDERIC J. COTTON,
Boston.

RICHARD B. DILLEHUNT,
Portland, Ore.

ELDRIDGE L. ELIASON,
Philadelphia.

LEO ELOESSER,
San Francisco.

GEORGE W. HAWLEY,
Bridgeport, Conn.

MELVIN S. HENDERSON,
Rochester, Minn.

JAMES M. HITZROT,
New York.

WILLIAM L. KELLER,
Washington, D. C.

ROY D. MCCLURE,
Detroit.

FRANK R. OBER,
Boston.

DALLAS B. PHENISTER,
Chicago.

J. SPENCER SPEED,
Memphis, Tenn.

The following subjects will be considered:

1. Plaster of Paris: Making and Storing.
2. Application of Plaster of Paris.
3. Fracture of the Lower End of the Radius.
4. Fracture of the Spine—Compression.
5. Fracture of the Ankle.
6. First Aid Treatment of Fractures of the Lower Extremities.

Demonstrations will be given continuously throughout the week. A special folder has been prepared for distribution in connection with the exhibit.

The following physicians will take part in the demonstration:

R. L. Anderson, Charleston, W. Va.
William Bates, Philadelphia, Pa.

G. I. Bauman, Cleveland, Ohio
J. Dewey Bisgard, Omaha, Neb.

John A. Brooke, Philadelphia, Pa.
Frement A. Chandler, Chicago, Ill.

Paul C. Colonna, New York, N. Y.
Harold R. Conn, Akron, Ohio

Edward T. Crossan, Philadelphia, Pa.
T. McKean Downs, Bryn Mawr, Pa.

John Dunlop, Pasadena, Calif.
Donald C. Durman, Saginaw, Mich.

E. L. Eliason, Philadelphia, Pa.
Harry Farrell, Philadelphia, Pa.

C. Fred Ferciot, Lincoln, Neb.
Eben W. Fiske, Pittsburgh, Pa.

L. K. Ferguson, Philadelphia, Pa.
J. A. Green, Rockford, Ill.

W. A. Hausman Jr., Allentown, Pa.
Drury Hinton, Drexel Hill, Pa.

Robert Impink, Philadelphia, Pa.
Paul N. Jepson, Philadelphia, Pa.

Louis Kaplan, Philadelphia, Pa.
J. M. King, Pittsburgh, Pa.

Orville C. King, Philadelphia, Pa.
Harry E. Knox, Philadelphia, Pa.

J. G. Kuhns, Boston, Mass.
Henry C. Marble, Boston, Mass.

James W. Martin, Omaha, Neb.
Thomas E. Meany, Chicago, Ill.

Henry Milch, New York, N. Y.
Frank G. Murphy, Chicago, Ill.

Earl D. McBride, Oklahoma City, Okla.

Jesse Nicholson, Philadelphia, Pa.
John Paul North, Philadelphia, Pa.

E. Payne Palmer, Phoenix, Ariz.
William Parker, Merion Station, Pa.

W. J. Potts, Oak Park, Ill.
Wells C. Reid, Goodrich, Mich.

Dean L. Rider, Chicago, Ill.
R. C. Robertson, Chattanooga, Tenn.

Norman S. Rothschild, Philadelphia, Pa.
William J. Ryan, Philadelphia, Pa.

Lemuel D. Smith, Milwaukee, Wis.
Calvin M. Smyth, Jr., Philadelphia, Pa.

Walter Stuck, San Antonio, Texas
Thomas J. Summey, Moorestown, N. J.

Horace E. Turner, Chicago, Ill.
D. R. Ulmer, Terra Haute, Ind.

Charles S. Venable, San Antonio, Texas
Jay D. Vyn, Grand Rapids, Mich.

Dudley P. Walker, Bethlehem, Pa.
Samuel J. Waterworth, Clearfield, Pa.

George Wagoner, Bryn Mawr, Pa.
I. R. Watkins, Aberdeen, Wash.

DeForest P. Willard, Philadelphia, Pa.
John H. Wolf, Germantown, Pa.

V. W. Murray Wright, Philadelphia, Pa.

SECTION EXHIBITS

Section on Practice of Medicine

M. X. SULLIVAN, Georgetown University, Washington, D. C.:

Biochemical Tests of Possible Clinical Value: Exhibit demonstrating colorimetric methods of estimating cystine in finger nails, urine and blood, and of glutathione and vitamin C in tissue and urine; charts presenting findings in health and disease, and covering references to published work.

CHARLES A. DOAN, BRUCE K. WISEMAN and CARL V. MOORE, Ohio State University, Columbus:

The Pathologic Physiology, Differential Diagnosis and Treatment of Hematologic Dyscrasias: Exhibit of graphs, charts and photomicrographs illustrating the following studies: lymphoblastomas and lymphadenopathy diseases, congenital hemolytic jaundice, thrombocytopenic purpura, agranulocytic angina, hypochromic microcytic and hyperchromic macrocytic anemias, polycythemia vera, tuberculosis; the cellular reactions to hyperpyrexia; data on bone marrow, blood volume and plasma iron studies; demonstration of the supravital method of staining and studying living blood and tissue cells.

J. RUSSELL TWISS, R. FRANKLIN CARTER and CARL H. GREENE, New York Post Graduate Hospital, New York:

Results of Treatment in Gallbladder Disease (Medical and Surgical): Exhibit of charts showing the results of medical and surgical treatment following specific treatment, which has

been based on a complete diagnostic work-up for the purpose of determining the indications for treatment in each case; the conclusions are the result of investigations carried on for the past seven years; motion picture.

J. W. CUTLER, Henry Phipps Institute, BAYARD S. HERR and F. R. PARK, Graduate Hospital, Philadelphia:

The Blood Sedimentation Test—An Aid in Diagnosis and Prognosis: Exhibit illustrating the fundamental characters of the blood sedimentation test; (1) it is nonspecific and occurs in many diseases characterized by disturbed stability of the blood; (2) it has distinct value as a diagnostic lead in indicating the presence of serious disease not infrequently before the disease can be recognized by the usual clinical and laboratory methods; (3) it also has value in diagnosis in a qualitative sense by indicating the intensity of the disease in the same sense as fever or pulse rate or blood count, but more exactly; (4) it is of distinct value in prognosis and as a guide in treatment, and will reflect more accurately the real condition of the patient than the usually accepted procedures; (5) the technic is simple and will give reliable and accurate results under average conditions.

J. WEST MITCHELL and PAUL L. McLAIN, Pittsburgh:

Peripheral Vascular Diseases: Demonstration of physiology and treatment. Exhibit of charts and paintings of principal peripheral vascular diseases with special reference to classification, differential diagnosis, and pulsation studies; working model of a leg showing arteries and veins in normal size and a capillary bed with a mechanical heart maintaining circulation of fluid through vessels, demonstrating hydrodynamics involved in (1) normal circulation, (2) occlusion of vessels at any given point, (3) vascular exercises (Buerger type).

EDWARD S. DILLON and W. WALLACE DYER, Philadelphia:

Diabetes Mellitus—Its Complications and Treatment: Exhibit of motion pictures and transparencies showing (a) coma and its treatment, gangrene and infection, the slow acting insulins; (b) standardization of the diabetic patient, treatment of insulin hypoglycemia and preoperative and postoperative care of the surgical diabetic patient, diabetic surgery, including leg amputation, toe amputation and incision of a carbuncle, the modern diabetic clinic, its organization and management; (c) a mannequin demonstration of the organization of a diabetic department; (d) placards illustrating (1) the increasing importance of diabetes mellitus from a public health point of view; (2) contributing causes of and the prevention of gangrene in the diabetic; (3) preparation of a modern diabetic diet.

HUGO FREUND, Harper Hospital, Detroit, and SAMUEL S. ALTSCHULER, W. J. Seymour Hospital, Eloise, Mich.:

Clinical Studies with Crystalline Insulin: Comparison of Standard, Crystalline, Protamine and Protamine Zinc: Exhibit of charts and tables showing (a) effect of crystalline insulin on blood sugar in the nondiabetic; (b) use of crystalline insulin in diabetic patients; (c) comparison of crystalline insulin with standard insulin; (d) comparison of crystalline insulin with protamine insulin; (e) zinc content of the different insulins, and (f) correlation of the insulin effects with their zinc contents.

H. L. SMITH, Mayo Clinic, Rochester, Minn.:

Fainting Spells Resulting from Hypersensitive Carotid Sinus Reflexes: Exhibit of motion picture showing attacks of syncope induced by stimulating the carotid sinus, with and without convulsions; the macroscopic and microscopic anatomy of the carotid sinus; mounted specimens of the carotid sinuses of different animals; photographs of the microscopic anatomy of the carotid sinus; records of animal experiments showing results of stimulation of the nerve of Hering by direct current, demonstrating the effect on heart rate, blood pressure and respiration; tracings showing respirations during induced attacks; electrocardiographic study showing effect of stimulation of the carotid sinus in patients with hypersensitive carotid sinuses, clinical diagnosis, prognosis and treatment.

ELMER L. DEGOWIN and W. L. RANDALL, Department of Internal Medicine, State University of Iowa, Iowa City:

Renal Damage from Blood Transfusion, Clinical Course in Man and Experimental Production in Dogs: Exhibit of transparencies depicting the clinical course and pathologic changes

in man developing anuria from blood transfusion; experimental work showing that hemoglobinuria in dogs with alkaline urines causes no renal lesions or chemical evidences of renal insufficiency; hemoglobinuria in dogs with acid urines causes precipitation and crystallization of pigment in renal tubules with consequent tubular obstruction and uremia.

EDWARD F. HARTUNG and Associates, New York:

The Treatment of Chronic Arthritis: Exhibit of pictures outlining the effective and generally recognized measures for treating chronic arthritis: constitutional therapy, diet, drug therapy, nonspecific protein therapy, hemolytic streptococcus vaccines and filtrates, orthopedic treatment, the correction of postural defects, and the relief of pain by nerve block.

MARTIN G. VORHAUS, New York:

Studies in Vitamin B₁: Exhibit showing effects of vitamin B₁ therapy in gout, various cases of osteo-arthritis and states of lowered metabolism; in addition a survey of the work of others in the same field is correlated showing the entire recent therapeutic indications of vitamin B₁.

JOHN D. CURRENCE and Associates, New York Post-Graduate Medical School and Hospital, Columbia University, New York:

Physical Therapy in Arthritis: Exhibit of pictures and graphs demonstrating the application of physical therapy (electrotherapy and hydrotherapy) in arthritis and the reactions to be expected on the blood sedimentation rate, red blood cell count, white blood cell count, hemoglobin, differential blood count.

JOSEPH FELSEN, New York:

Intestinal Manifestations of Systemic Disease and Their Clinical Significance: Exhibit showing that the intestine may be regarded as possessing a dual excretory mechanism comprising (1) the direct intestinal excretory route and (2) the indirect hematogenous excretory route. The dual excretory mechanism of the intestine is intimately linked with that of the kidneys, skin and lungs, the tetrad constituting what may be termed the reciprocal excretory mechanism of the body. Intestinal manifestations in systemic disease are the result of the related action of these two mechanisms. The lesions produced are shown in the following diseases: leukemia, agranulocytosis, staphylococci, streptococci, pneumococci and meningococci bacteremias, chorionepithelioma, arteriosclerosis, rheumatic intestinal necrosis, periarteritis nodosa, bacillary dysentery, amebiasis, tuberculosis, pharyngogenic hematogenous streptococci peritonitis, plumbism, status lymphaticus, toxic lymphoid hyperplasias. The following diagnostic and therapeutic procedures are demonstrated: intestinal transilluminator, the use of color filters in sigmoidoscopy, intermittent intestinal aspiration.

EDWIN E. OSGOOD and INEZ BROWNLEE, Division of Experimental Medicine, University of Oregon Medical School, Portland, Ore.:

The Culture of Human Marrow: Exhibit demonstrating the methods developed for the culture of human marrow; an improved apparatus which provides the functions of a heart, lung and kidney for tissue culture; charts, colored illustrations and microscopic slides from the marrow cultures showing the progress which has been made toward the solution of the problems involved; mitotic figures, phagocytosis of bacteria and erythrocytes, evidence for in vitro deposition of hemoglobin, and living, moving cells demonstrated under microscopes; chart showing the histogenesis of the leukocytes and erythrocytes and a proposed simplified nomenclature based on evidence from marrow cultures; problems which offer promise of solution by this method outline; culture characteristics of marrow from patients with leukemias and anemias compared with those of normal marrow.

WILLIAM DAMESHEK and HENRY H. HENSTELL, Boston:

The Sternal Bone Marrow Biopsy; Trephine and Puncture Method: Exhibit dealing with (1) the trephine method: technic; types of preparations obtained: sections, smears, sections useful for general topography, degree of cellularity, visualization of abnormal cellular islands; smears valuable for differential counts and study of individual cells; biopsy of greatest value in cases presenting obscure anemia, especially those with reduction in white cells and platelets; illustrative cases with descriptions

of blood and bone marrow pictures and final diagnosis: (aleukemic leukemia, sarcoma and other malignant conditions metastasizing to marrow, Hodgkin's disease, aplastic anemia, pernicious anemia; (2) the puncture method: technic; type of preparation obtained; comparison of results with trephine method; limitations and disadvantages; advantages; (3) correlation of bone marrow and blood picture; study of bone marrow in various conditions; the importance of understanding the pathologic physiology "behind" the blood picture.

SYMPOSIUM ON PNEUMONIA

The symposium on pneumonia is presented by the Section on Practice of Medicine under the guidance of a committee composed of Donald B. Armstrong, Russell L. Cecil and Fred M. Smith, chairman. The following exhibits and talks will be given:

JESSE G. M. BULLOWA, CLARE WILCOX, BENJAMIN WOLFMAN, HERMAN D. RATISH and EVELYN GREENBAUM, New York:

Management of the Pneumonias: Exhibit of charts showing results of serum treatment and methods of using serum, including therapeutic rabbit serum; methods of administering oxygen without a tent; treatment of pulmonary edema with sucrose; indications for other therapeutic measures; pneumococcus typing.

RUSSELL L. CECIL, LOUIS I. DUBLIN and DONALD B. ARMSTRONG, Metropolitan Life Insurance Company, New York:

Pneumonia Control: Exhibit of charts, graphs and specimens showing incidence and distribution of pneumonia; etiology, diagnosis, serum therapy, prognosis, pathology and the requirements of a public health program, emphasizing the need for early diagnosis and skilled medical and nursing care.

Lectures on Pneumonia: Special talks and lectures will be given throughout the week in an area adjoining the exhibits.

Section on Surgery, General and Abdominal

GROUP EXHIBIT: Frank H. Lahey and Associates, Lahey Clinic, Boston:

Transilluminated drawings and roentgenograms of various surgical and clinical subjects, as follows: (1) esophageal pulsion diverticulum, two stage operation; (2) total and subtotal gastrectomy; (3) common diseases of the stomach; (4) intrathoracic goiter, intratracheal anesthesia; (5) sciatica diagnosis and management; (6) bronchoscopic diagnosis of carcinoma of the lung; (7) subdural hematoma; (8) trifacial neuralgia, diagnosis and management.

WILLIAM J. HOFFMAN, New York:

Treatment of Cancer by Surgery and Irradiation: Exhibit of transparencies illustrating methods employed in the treatment of cancer in various regions of the body, including cancer of the lip, tongue, tonsil, pharynx, breast, metastatic nodes, skin and cervix; demonstration of the combinations of surgery and radiation in the treatment of cancer and to some extent the indications for surgery or irradiation in the modern treatment of cancer.

JOHN S. LUNDY, L. H. MOUSEL, E. B. TUOHY and R. C. ADAMS, Mayo Clinic, Rochester, Minn.:

Technic of Regional Anesthesia: Exhibit showing the technic of deep and superficial cervical, brachial, paravertebral, intercostal, peridural, spinal, posterior splanchnic, dorsal sympathetic, lumbar sympathetic, sacral, caudal, trigeminal and mandibular block anesthesia and block to facilitate operation for cataract by means of life size models; in one model the left half of the entire back shows the important superficial landmarks for the points of approach, while the other half shows a dissection down to the level and including the spinal cord and its branches, thus making it possible to show the site at which the solution is deposited in each type of block anesthesia.

C. LATIMER CALLANDER, San Francisco:

Surgical Anatomic Specimens Illustrating a New Amputation Through the Femur at the Knee: Exhibit of charts, drawings, photographs and dissected specimens illustrating anatomy of the knee regions, as well as depicting steps in the amputation.

GEORGE A. WYETH, New York:

Cancer Cases Treated by Electrosurgery: Exhibit of photographs of cases with equipment illustrating (1) that it is now possible to know before beginning treatment or in time to be of value to the patient (a) what kind of a tumor it is, (b) the degree of its malignancy, (c) whether it is a radiosensitive or a radioresistant tumor; (2) that electrosurgery is merely an adjunct in the treatment of these cases and is solely a matter of technic; (3) that this technic extends the limits of operability in cancer cases; (4) that a certain permanence follows this technic.

A. C. SCOTT JR., Scott and White Hospital, Temple, Texas:

Retrotracheal Thyroid Projections; Relationship to Recurrent Exophthalmic Goiter: Exhibit of statistics, drawings, charts and mouldages showing pathologic specimens of enlarged thyroid gland; diagrammatic mouldages demonstrating the position of the esophagus and trachea in relation to the enlarged thyroid and its retrotracheal lobes; motion picture film demonstrating the retrotracheal thyroid projections.

ELLIOTT C. CUTLER and ROBERT ZOLLINGER, Peter Bent Brigham Hospital, Boston:

The Technic of Common Surgical Procedures: Exhibit of pen and ink drawings illustrating in detail the various steps of the common surgical operations as carried out at Peter Bent Brigham Hospital.

N. FREDERICK HICKEN and R. RUSSELL BEST, Omaha:

Mammography: The Roentgenographic Diagnosis of Breast Tumors by Contrast Visualization: Exhibit of contrast roentgenograms demonstrating an effective method of visualizing the breast, showing that, if such radiopaque substances as stabilized thorium dioxide sol, lipiodine and carbon dioxide are introduced into the milk ducts, the resulting stereoscopic roentgenograms give an accurate anatomic pattern of the injected ducts; any pathologic condition which alters the size, shape or configuration of the ductal pattern can be readily detected; lipoma, fibrolipoma, papilloma, carcinoma, cysts, abscesses and galactoceles have been diagnosed by these visualization studies; contrast mammograms afford an excellent method of studying the physiologic changes that occur in the mammary gland during puberty, pregnancy, lactation and the menopause; the technic employed and the diagnostic value of these visualization studies are portrayed by transparencies, mouldages, stereoscopic mammograms and motion pictures.

G. M. DORRANCE, J. W. BRANSFIELD and J. H. GUNTER, Philadelphia:

Fractures of the Jaws: Exhibit of photographs and roentgenograms showing methods of treating fractures from the earliest times up to the present day, such as bandaging, external appliances, extra-oral and intra-oral appliances, monomaxillary splint, intermaxillary splint, wire bands and bone grafts, with comments on each group and each method; photographs illustrating the different variety of fractures; classifications, detailed description and illustration of the different methods for treating each fracture.

CLAIRE L. STRAITH and WILLIAM A. LANGE, Detroit:

Plastic Surgery, Especially in Automobile Injuries: Exhibit showing that if the application of the principles of plastic surgery were applied to the treatment of traffic accident wounds at the first treatment or operation it would greatly minimize the resultant scars and leave fewer deformities; demonstration of many of these principles in detail and the correction of other deformities with which the practitioner comes in contact; several simplified methods of treating facial bone fractures which can be used by any surgeon without special equipment.

HILGER PERRY JENKINS, Department of Surgery, University of Chicago, Chicago:

Catgut Absorption: An Experimental and Clinical Study: Exhibit dealing with the absorption of chromic catgut of different sizes and brands in the tissues under varying conditions; digestion tests of catgut and the relationship between the digestion time in acid pepsin and the duration in the tissues; the effect of gastric juice on catgut absorption; etiologic factors in abdominal wound disruption and the significance of the absorption time of catgut used in abdominal wound closure.

ROBERT E. MORAN, Georgetown Medical School, Washington, D. C.:

Plastic Surgery: Exhibit demonstrating a new operation for exophthalmos, "lateral decompression of orbit"; correction of enophthalmos with cartilage transplants; a new operation for webbed fingers using buried full thickness grafts; plastic operations about orbit, nose, mouth and neck; comparison of full thickness grafts and pedicle grafts to hand and weight bearing surfaces; a group of buried grafts under scar tissue and granulations; animated motion pictures and model of (mechanism) exophthalmos in exophthalmic goiter.

NORMAN E. FREEMAN, Harrison Department Research Surgery, University of Pennsylvania, Philadelphia:

The Peripheral Blood Flow in Surgical Shock: Exhibit showing the method used for the determination of the volume flow of blood through the hand; charts presenting the normal blood flow and the effect of cold, pain, fear and asphyxia on the peripheral circulation; the reduction in the flow of blood which was found in clinical cases of surgical shock is illustrated; by means of a motor-driven circulatory schema, the relationship between blood volume, heart rate, blood pressure and blood flow is shown.

JAMES A. JACKSON and JEROME T. JEROME, Jackson Clinic, Madison, Wis.:

Bone Surgery: Exhibit of (a) transparencies demonstrating various types of injuries, including special instruments and appliances used in their management; (b) transparencies showing bone tumors in various classifications; (c) charts and diagrams illustrating aspects of these subjects.

HERBERT L. JOHNSON, Boston:

Absorbable Sutures and Insulating Patches Made from Human and Bovine Fetal Membranes: Exhibit of gross and microscopic specimens of animal tissues showing comparative local reaction and absorption rate of insulating patches and spun sutures made from bovine allantoic membrane versus: patches and sutures made from "catgut," human amniotic membrane and animal peritoneum; drawings of cow's gravid uterus depicting arrangement of the fetal membranes; posters and legends, viewing boxes and colored transparencies.

ARNOLD S. JACKSON and J. NEWTON SISK, Jackson Clinic, Madison, Wis.:

Diseases of the Gastro-Intestinal Tract: Exhibit of charts, drawings and paintings depicting cancer of the stomach, diseases of the gallbladder, cancer of the large and small intestine, intestinal regional enteritis, appendicitis and perforating ulcer; statistical records detailing symptoms, operative observations and postoperative results are presented; models demonstrating various lesions; lantern slides and motion pictures presenting operative technic.

WALTER G. MADDOCK and FREDERICK A. COLLIER, University Hospital, Ann Arbor, Mich.:

Water Balance in Surgery: Exhibit of charts and graphs showing the results of a study on the water requirements of surgical patients. The sources of available water and its excretion in health are dealt with; the water losses of patients under various aspects of disease and treatment are presented, the data being used to show the water needed under these conditions; the kind of fluid to administer when parenteral fluids are needed is brought out by data from the use of the common intravenous solutions; emphasis is placed on the need for thought as to both the amount and the kind of fluid to administer in each individual patient requiring parenteral fluids.

H. A. GAMBLE and JOHN A. BEALS, Greenville, Miss.:

The Open Wound Treatment of Peritonitis: Exhibit of transparencies and motion picture in color illustrating the method of treating diffuse peritonitis especially secondary to appendicitis; focus of infection is removed; Penrose drains are introduced; the peritoneum is sutured down to the drains; stay sutures of silver wire support the abdominal wound, which is left entirely open to the air without dressings until healed; the method prevents anaerobic infection of the abdominal wall, and the mortality rate has been reduced to 1.5 per cent.

BERNHARD STEINBERG, Toledo Hospital, Toledo, Ohio:

Developmental Mechanism of Peritonitis: Exhibit showing the tissue reaction together with the changing picture of the peritoneal exudate throughout the course of diffuse experimental peritonitis; the peritoneal exudate picture is correlated with the peripheral blood and the general condition of the animal; the cause of death is shown by experiments; the condition of the cardiovascular system is exemplified by electrocardiographic tracings and continuous blood pressure throughout the entire course of peritonitis is demonstrated; the principles of preventive and curative treatment are drawn from the anatomic and abnormal physiologic changes observed during the experiments; suggestive therapeutic measures, both preventive and curative, are shown.

W. L. ESTES JR. and H. A. ROTHROCK JR., Bethlehem, Pa.:

Partial Cholecystectomy: Exhibit of motion pictures showing the operation of partial cholecystectomy; charts of steps in operation; chart of indications and statistics.

J. ROSS VEAL, Louisiana State University Medical Center, New Orleans:

Arteriosclerosis and Arteriosclerotic Gangrene: Exhibit of colored drawings, supplemented by arteriographs showing arteriosclerosis in its various stages; the treatment of the various stages; the methods of determining the lowest limits of adequate circulation and the factors in the mortality rate.

CHARLES S. WHITE and J. LLOYD COLLINS, George Washington University School of Medicine, Washington, D. C.:

Empyema Thoracis: Exhibit of motion pictures, charts, graphs and roentgenograms showing a comparative study of methods of treatment of empyema thoracis.

WILLIAM BATES and BERNARD D. JUDOVICH, Philadelphia:

Parietal Pain: Exhibit of charts and motion pictures of clinical cases presenting the etiology, diagnosis and treatment of parietal pain; clinical tests to differentiate between acute appendicitis and acute parietal pain; the futility of multiple operations in cases of so-called postoperative adhesions; parietal pain, with special reference to backache and abdominal symptoms; the lumbodorsal spine and its frequently undiagnosed involvement in low back pain and lower quadrant abdominal pain.

THOMAS A. SHALLOW and K. E. FRY, Jefferson Hospital, Philadelphia:

Diverticula of the Pharynx: Exhibit of transparencies of roentgenograms of diverticula; charts enumerating the symptoms and diagnostic methods, drawings and charts showing the technic of the one stage combined operation; mounted specimens of diverticula removed at operation; motion pictures.

W. EMORY BURNETT, Philadelphia:

Lobectomy-Pneumonectomy Under Local Anesthesia: Exhibit of transparencies with the mounted specimen in a lighted compartment; charts on diagnosis, type of anesthesia, mortality statistics of large groups of recent cases of pneumonectomy and lobectomy.

HAROLD L. FOSS, Geisinger Memorial Hospital, Danville, Pa.:

Diagnosis of Diseases of the Thyroid Gland: Exhibit of transparencies of thyroid tissues, both gross and microscopic films illustrating the various types of thyroid disease, emphasizing the importance of differentiating adequately between the different types of goiter with associated toxemias.

Section on Obstetrics, Gynecology and Abdominal Surgery

JACOB HOFFMAN, Philadelphia:

Operation of a Gynecologic Endocrine Clinic for Diagnosis and Treatment of Menstrual Disorders and Sterility: Exhibit of (1) photomicrographs showing histologic changes in ovary and endometrium: (a) during the normal menstrual cycle; (b) associated with functional menstrual disturbances; (2) tests of sex hormone content of blood and urine for estimation of ovarian function: (a) apparatus used; (b) gross and microscopic reaction of test animals (photographs); (c) interpretation of observations; (3) photographs of endocrine and constitutional types commonly encountered in gynecologic endocrine

clinic; (4) charts showing: (a) methods of diagnosis and treatment; (b) results obtained; (c) evaluation of diagnostic methods and treatment.

RICHARD TORPIN, University of Georgia School of Medicine, Augusta, Ga.:

A Device for Simplifying Thoms Method of Roentgenographic Pelvimetry: Exhibit showing a device which will mark and fix in space the plane of the external conjugate; a leaden plate perforated every centimeter is mechanically held in this plane and the holes are photographed on the same film and with the same distortion as the superior strait; all the dimensions of the strait can thus be measured without calculation.

ROBERT GREENBLATT and EVERETT S. SANDERSON, University of Georgia Medical College, Augusta, Ga.:

Bacillary Antigen for Intracutaneous Test in the Diagnosis of Chancroid: Exhibit of charts showing the results of many tests; comparison with dmeclos preparation, including pictures of the skin tests; vials of antigen and mediums for culturing *Haemophilus ducreyi*; photograph of *H. ducreyi* as observed in cultures; photographs of lesions for differential diagnosis.

W. F. HAMILTON, R. A. WOODBURY and A. K. TEMPLES, University of Georgia School of Medicine, Augusta, Ga.:

Differential Pressures in Parturition: Exhibit showing a differential optical manometer, making it possible to record optically and quantitatively the separate contributions of the uterus and abdominal walls to the expulsive effort; in addition to the systemic blood pressure, the effective head of blood pressure supplying the placenta and the abdominal organs can be measured from separate simultaneous optical records.

PAUL TITUS, R. H. MCCLELLAN and B. R. ALMQUEST, St. Margaret Memorial Hospital, Pittsburgh:

Study and Treatment of Human Sterility: Exhibit covering study of causes of relative sterility in female and male shown by record forms and illustrations; commoner genital anomalies, types of cervicitis, technic of tubal insufflation and roentgen visualization of the uterus and tubes, endometrial biopsies for evidence of ovulation, and technic of sex hormone estimation; spermatic fluid studies, including motility studies and technic of total and differential counting of spermatozoa; technic of treatment of relative sterility and operative treatment; diagnosis and treatment of absolute sterility.

CHARLES MAZER, S. LEON ISRAEL and CHARLES W. CHARNY, Philadelphia:

Etiology and Treatment of Sterility: An analysis of 400 barren marriages. Exhibit of motion pictures showing a statistical study of cases of sterile marriage from the standpoint of etiology, treatment and results; the various procedures employed in determining the degree of fertility of both mates, such as examination of semen, intra-uterine insufflation, the Huhner test and premenstrual biopsy of the endometrium; photographs of patients, depicting various endocrinopathies responsible for the associated menstrual disorders.

WILLIAM BIERMAN and E. A. HOROWITZ, New York:

The Treatment of Gonorrhea in Women by Means of a Combined Heating Technic: Exhibit of charts and illustrations showing technic, its rationale, and results obtained; the treatment of gonorrhea in women by means of a combined heating technic; changes in the cervical and urethral secretions; exhibition of special vaginal electrodes; motion picture illustrating technic.

HENRY C. FALK, New York:

The Infected Abortion—A Clinicopathologic Study of Its Diagnosis and Management: Exhibit of drawings in color showing various types of postabortal infection; paths by which infection travels; lesions produced by the various types of infection; methods of recognizing the various types, showing typical temperature charts and a description of the management of various types.

MORTIMER A. HYAMS, New York:

Serial Uterosalphingography—The Roentgenographic Visualization of the Uterus and Fallopian Tubes by Fractional Injection, an Innocuous Procedure of Particular Diagnostic Value

in the Delineation of Obscure Gynecologic Conditions: Exhibit demonstrating the procedure; equipment, instruments used; the value and advantages of this method shown by comparative studies of uterosalphingograms taken preoperatively with studies of the uteri removed at operation; uterosalphingograms of conditions that could be diagnosed only by this method, illustrated with special films in illuminating boxes.

FRANKLIN F. SNYDER and MORRIS ROSENFELD, Johns Hopkins Hospital, Baltimore:

Intra-Uterine Respiration of the Fetus and Its Relation to Respiratory Failure at Birth: Exhibit of motion pictures supplemented by charts and photographs to illustrate (1) intra-uterine respiratory movements of the human fetus; (2) chemical regulation of fetal breathing and the changes occurring at birth; (3) failure of fetal respiration due to anesthesia and anoxemia; (4) breathing of amniotic fluids as a normal function of fetal respiration, its significance in dilatation of the air passages before birth and its relation to the pathology of the lung.

MOTION PICTURE PROGRAM

In an area adjoining the exhibits of the section, motion pictures on obstetrics, gynecology and abdominal surgery will be shown on a definite schedule throughout the week.

EVERETT I. EVANS—*Ovulation, Fertilization and Early Development of Mammalian Ovum.*

C. O. MCCORMICK—*Analgesia in Labor—Modified Gwathmey Technic.*

E. D. PLASS—*Gestational Polyneuritis.*

FRED L. ADAIR—*Treatment of Uterine Prolapse by the Le Fort Colpocleisis Procedure.*

WILLIAM J. DIECKMANN—*Blood Transfusion.*

Section on Ophthalmology

JOHN OLIVER McREYNOLDS, Dallas, Texas:

Illustrations of Various Eye Operations: Exhibit of motion pictures illustrating important eye operations and photographs showing specimens of the crystalline system and intra-ocular tumors; legends and personal demonstrations.

CONRAD BERENS, JACOB A. GOLDBERG and BRITTAIN F. PAYNE, National Society for the Prevention of Blindness and New York Tuberculosis and Health Association, New York.

Syphilis and the Eye: Exhibit consisting of (1) charts based on a study of 100,000 case records made by the Committee on Study of Syphilis and Eye Diseases, New York Tuberculosis and Health Association; (2) transparencies illustrating syphilitic eyes; (3) a mounted display; (4) slides on syphilitic eye conditions.

A. E. BRALEY, P. J. LEINFELDER and C. S. O'BRIEN, University Hospitals, Iowa City:

Orbital Tumors: Exhibit demonstrating the clinical diagnosis and the pathology of twenty-two different types of orbital tumors; transparent colored photographs illustrate the clinical appearance and the microscopic changes; charts show the relative frequency of occurrence and the differential diagnosis.

GEORGE GUIBOR and GEORGE E. PARK, Chicago:

A Classification of Concomitant Strabismus with Reference to Treatment: Exhibit of charts and photographs dealing with a classification of concomitant strabismus, the purpose of which is to differentiate those types of strabismus amenable to non-surgical training from those amenable to surgery; the characteristics of each type of squint, and the average number of cases recovering cosmetically from the appropriate treatment are shown.

ROBERT M. STECHER and BENJAMIN J. WOLPAW, City Hospital, Cleveland:

Artificial Fever Therapy of Ocular Diseases: Exhibit of photographs demonstrating the appearance of the eye in various ocular diseases and showing the changes that occur following fever therapy; the diseases illustrated include interstitial keratitis, gonorrheal ophthalmia, rheumatic iritis and hypopyon; essential facts of the clinical history, details of the treatment administered, and description of the changes seen are included in labels for each picture.

HARRY S. GRADLE, Department of Public Welfare and Illinois Society for the Prevention of Blindness, Chicago:

Trachoma: Exhibit of living conditions, individual cases and trachoma clinics in Illinois; an illuminated map of the southern fourteen counties of Illinois showing the bus runs to the clinics; statistical tables.

MARTIN COHEN, New York:

Fundus Lesions in Essential Hypertension and in Arterial and Renal Disease: Exhibit of colored fundus drawings of clinical cases accompanied with a brief history of each case, including colored drawings of microscopic sections of the kidneys of a few of these cases; the vascular lesions with their complications have been accurately drawn in each case.

GEORGE K. SMELSER, New York:

Experimental Production of Exophthalmos Similar to That Found in Exophthalmic Goiter: Exhibit consisting of (1) photographs of experimental animals demonstrating the degree and nature of the exophthalmos; (2) charts dealing with the changes induced in the orbital tissue of these cases; (3) photomicrographs of tissues removed from orbits in experimental and clinical cases of exophthalmos; (4) demonstration of pathologic condition found in the orbital tissues of clinical and experimental exophthalmos by means of microscopes and slides; (5) natural color photomicrographs of orbital tissues removed from both experimentally produced and clinical cases of exophthalmos.

HARVEY D. LAMB, St. Louis:

Pathology of the Human Eyeball: Exhibit of photomicrographs of particularly typical or unusual pathologic conditions of the human eyeball including corneal ulceration (one from aspergillus) and various sequelae: various forms of staphylococci, types of pannus, some developmental corneal changes, formation of precipitates on back of cornea, tuberculosis of choroid and optic papilla, sympathetic uveitis, unusual forms of melanosis of choroid, glioma of retina and glaucoma, with study of trephine wound at various intervals after operation.

A. B. REESE, Institute of Ophthalmology, New York:

Ocular Tumors and External Diseases: Exhibit A consists of colored drawings showing the clinical appearance for comparison with photomicrographs of the sections; exhibit B consists of colored drawings and photographs.

EDMUND B. SPAETH, Philadelphia:

The Surgical Correction of Ptosis: Exhibit of photographs and drawings, with a motion picture film illustrating the various conditions demanding correction.

MOTION PICTURE PROGRAM

In an area adjoining the exhibits, motion pictures on ophthalmology will be shown on a definite schedule throughout the week.

THEODORE J. DIMITRY—*Animated Diagrams Depicting Cataract Extraction.*

CONRAD BERENS—*Routine Examination and Treatment of Motor Anomalies Employed in the Department of Motor Anomalies of the New York Eye and Ear Infirmary.*

LOUIS LEHRFELD—*Allergic Agents in the Eye.*

RAMON CASTROVIEJO—*Dacryocystorhinostomy; Intracapsular Cataract Extraction; Keratoplasty, and Elliott's Trephine.*

Section on Laryngology, Otology and Rhinology

MAX CUTLER and L. M. ROSENTHAL, Michael Reese Hospital, Chicago:

Treatment of Intra-Oral Cancer: Exhibit of photographs, motion pictures, charts and models illustrating the following symposium on intra-oral cancer: (a) anatomic distribution, (b) course of disease, (c) histologic studies, (d) classification, (e) methods of treatment (technic of irradiation), (f) results.

HENRY B. ORTON, Newark, N. J.:

Cancer of the Larynx: Exhibit showing larynges that have been removed by operation; colored pictures of the larynx together with photomicrographs of the lesion and photographs of patients alive and well; the importance of cancer at the present time.

SAMUEL IGLAUER, Cincinnati:

Roentgenologic Studies of the Neck and Posterior Mediastinum: Exhibit of roentgenograms illustrating (1) normal anatomy of the neck in males and females at various ages; (2) the normal anatomic relationship of the superior and posterior mediastinum; (3) swellings due to infection of soft parts; i. e., retropharyngeal abscess, retro-esophageal mediastinitis, cellulitis, and so on; (4) tumors in the neck and mediastinum; (5) interstitial emphysema following perforation of the pharynx or esophagus; (6) methods of demonstrating the presence of opaque and nonopaque foreign bodies in the pharynx, larynx, trachea and esophagus; (7) the seating of appliances used in the treatment of laryngeal stenosis.

EDWARD C. ARMBRECHT, Wheeling, W. Va.:

Oral Surgery: Exhibit comprising photographs taken before and after operation of oral surgical conditions found in patients, such as (1) jaw fractures; (2) oral tumors; (3) cleft lip and cleft palate; (4) miscellaneous (comprising impacted teeth, unusual tooth deformities, oral manifestations of certain systemic diseases, foreign bodies found in the mouth, and so on).

M. H. LURIE, Boston:

Causes of Deafness in Animals: Exhibit of photomicrographs of animals' ears showing pathologic conditions found causing deafness; types of deafness found in these animals are (1) middle ear deafness; (2) nerve deafness; (3) inherited deafness; (4) deafness due to traumatic injuries to the ear.

RAPHAEL SCHILLINGER, Brooklyn:

Mastoids and Sinuses: Correlation of Clinical and Roentgen Studies: Exhibit of roentgenograms, clinical notes, charts, diagrams and bone specimens, demonstrating the value of roentgenologic procedures in the diagnosis and treatment of mastoiditis and sinusitis; the development of the mastoid process is traced roentgenographically from infancy, thus permitting an anatomic classification of mastoids based on development; film interpretation is correlated to the histopathologic changes; the use of the roentgen ray as a therapeutic and prophylactic agent is discussed; an "opaque survey" of the nasal sinuses is described, showing the importance of studying the sinuses functionally with the aid of radiopaque mediums and pointing out the inadequacy of the simple, so-called standard examination; clinical, pathologic and operative data are shown.

EVAN G. GALBRAITH, Toledo Hospital, Toledo, Ohio:

Experimental Bronchial Obstruction: Exhibit showing methods of producing complete and incomplete bronchial obstruction with and without injury to the bronchial mucosa; the anatomic changes in the lung followed at frequent intervals; both gross and microscopic changes of the various stages and to the various types of obstruction recorded; the effect on the pulmonary and bronchial circulation incident to the obstruction determined at frequent intervals; the return to normal, both from the anatomic and the physiologic point of view, after removal of the foreign body; methods of treatment decided from the experimental observations suggested.

WELLS P. EAGLETON, Newark, N. J.:

Intradural Complications from Petrous Apex Suppuration: Exhibit of mounted specimens of intracranial complications of the petrous apex suppuration; bones, brains and a series of roentgenograms showing the condition before death; history of each case.

L. H. CLERF and B. L. CRAWFORD, Jefferson Hospital, Philadelphia:

Benign Tumors of the Bronchus: Exhibit of prints of x-ray films, photomicrographs, charts and specimens of pathologic material directing attention to certain benign tumors that often are confused with carcinoma of the bronchus.

Section on Pediatrics

CHARLES C. CHAPPLE and JOSEPH STOKES JR., Children's Hospital, Philadelphia:

An Incubator for New-Born and Premature Infants: Exhibit showing an incubator with an air-tight heat-insulated chamber which utilizes outside air complete with temperature control,

humidity control and air-lock so that the infant need not be removed for any routine maneuver, as clysis, gavage, enema, weighing or feeding.

ADOLPH G. DESANTIS, FRANCIS D. MCCORMICK, LESLIE O. ASHTON, OLIVER L. STRINGFIELD and EDWARD DENNEEN, New York:

Appendicitis in Children: Exhibit of charts, anatomic drawings, anatomic models, photographs and series of case reports dealing with the question of diagnosis and management of appendicitis in infancy and childhood; diagnosis and pathology are stressed and various factors entering into the mortality rate are reviewed.

M. BERNARD BRAHDY and C. A. GAFFNEY, Willard Parker Hospital, New York:

Rapid Method for the Diagnosis of Diphtheria: Exhibit of (1) photomicrographs from stained smears from four hour (rapid method) cultures taken from diphtheritic membranes; (2) charts showing comparative results of rapid method and Loeffler method in diphtheria cases and controls; (3) photomicrographs of stained smears from rapid method transplants for obtaining pure culture for virulence tests in carriers; (4) charts showing higher percentage of identification of virulent carriers by the new method; (5) culture tubes for new rapid method; (6) demonstration of stained smears from rapid method cultures.

THEODORE O. ELTERICH, Pittsburgh:

Problems in the Endocrinology of Childhood: Exhibit of (1) female pseudohermaphroditism with adrenal hyperplasia and atypical precocious maturation in two siblings, roentgenograms, drawings, data on what was found at operation, histology of ovary, etc. (2) Varying types of precocious puberty, illustrated by (a) two cases of precocious menstruation; one child followed for a period six years, one child operated on, with report of observations; (b) a girl of 6 years undergoing precocious maturity of a masculine type; (c) precocious puberty in some forms of pseudohermaphroditism. (3) Cretinism. (4) Differential points in diagnosis between mongolism and juvenile myxedema (cretinism). (5) Hypogonadism. (6) Several types of pituitary dysfunction: (a) adipositas gigantismus, (b) dwarfism, (c) Hand-Schüller-Christian's disease with diabetes insipidus.

CLIFFORD SWEET, Oakland, Calif.:

The Teaching of Body Mechanics in Pediatric Practice: Exhibit of slides, photographs and motion pictures illustrating the fundamentals of body mechanics in relation to age and growth of children; simplified practical method of teaching body mechanics to parents and children is shown.

T. WINGATE TODD, Western Reserve University, and MILTON B. COHEN, Asthma and Hay Fever Clinic, Cleveland:

The Allergic Crippled Child: Exhibit of charts and manikins showing the effects of allergy in the physical and mental developmental growth pattern and of roentgenograms that demonstrate (1) tonsils, adenoids and turbinates, (2) growing and mutilated faces, (3) scorings, scars and demineralizations, and (4) maturation and its vagaries.

I. NEWTON KUGELMASS and S. C. MILLER, New York:

The Clinical Control of Dental Caries in Children: Exhibit presenting the method of determining the life caries index; type of caries in deciduous and permanent teeth; classification of dental caries in children; correlation of the degree of dental caries according to anatomic age, developmental trend, endocrine pattern, nutritional status, infectious invasion and mouth hygiene; the prevention of hereditary nutritional, metabolic, endocrine and infectious types of dental caries; the management of dental caries as a metabolic disorder in children.

GEORGE M. RETAN and KATHRYN S. RETAN, Syracuse University and Syracuse Memorial Hospital, Syracuse, N. Y.:

Perivascular Drainage for Infections of the Central Nervous System: Exhibit of charts relating to theoretical considerations, procedure and a summary of results in various diseases in which perivascular drainage for infections of the central nervous system is useful; model of set-up for treatment and a continuous motion picture.

MATTHEW WINTERS, CHARLES A. TOMPKINS and GRACE WASHBURN, Indianapolis:

The Use of a Pectin-Agar Preparation in the Treatment of Infant Diarrhea: Exhibit demonstrating therapeutic food, its composition, mode of preparation and forms of administration; tabulations of clinical results with comparison to other treatments will be shown; placards giving pertinent information on the present thought on fruit and allied diets in the treatment of diarrhea as based on a complete review of the literature on pectin, agar-milk diets and fruit diets.

Section on Pharmacology and Therapeutics

D. L. TABERN, HENRY C. SPRUTH and RICHARD KOHN, Abbott Laboratories, North Chicago, Ill.:

Studies on the Newer Barbiturates: Exhibit of charts, models and colored motion pictures illustrating certain interesting properties of the more recently developed barbiturates, such as rate of onset of action, duration of action, influence on blood pressure and respiration, use in connection with other forms of anesthesia and tranquilizing action, primarily from the standpoint of chemistry and pharmacology; other original studies on a group of substances having analeptic properties and their action during barbiturate hypnosis.

R. N. HARGER, H. R. HULPIEU and E. B. LAMB, Department of Biochemistry and Pharmacology, Indiana University School of Medicine, Indianapolis:

Prediction of Brain Alcohol from the Alcohol Content of Other Body Tissues and Fluids and Breath: Exhibit of charts and graphs covering recent original work showing the distribution of alcohol in brain, blood, liver, muscle, alimentary tract, spinal fluid and breath; time needed to reach alcohol storage equilibrium in various parts of the body; rôle of tissue water in the storage of alcohol.

THEODORE KOPFANYI and CHARLES R. LINEGAR, Georgetown University School of Medicine, Washington, D. C., and JAMES M. DILLE, University of Washington, Seattle:

Detection, Pharmacologic Action and Toxicology of Barbiturates: Exhibit of reagents and technic of procedure used in the detection and estimation of barbiturates in drug mixtures, urine, blood and organs; charts containing a diagrammatic description of these procedures; charts and drawings showing the fundamental pharmacologic actions of barbiturates; motion picture showing the depressant actions of barbiturates and the antagonism between barbituric acid derivatives and picrotoxin.

MARVIN R. THOMPSON, University of Maryland, Baltimore:

Ergot and Its Active Principles: Exhibit demonstrating the action of the various active principles of ergot on isolated surviving smooth muscle, using kymograph recording; charts illustrating the chemistry and pharmacology of ergot and its U. S. P. and N. F. preparations, with emphasis on pharmacologic and chemical standardization procedures.

ABRAHAM MYERSON, JULIUS LOMAN, MAX RINKEL, MAX RITVO and P. G. SCHUBE, Research Laboratory, Boston State Hospital, Boston:

Autonomic Pharmacology of the Human Being: Exhibit consisting of replicas of experiments on sweating, blood pressure, pulse rate, heart activity, gastro-intestinal secretion, gastro-intestinal motility, urinary bladder activity, eye and Argyll Robertson pupil, with charts, electrocardiograms, x-ray slides and other evidences of the results obtained, including samples of gastric juice.

PAUL STARR, Northwestern University Medical School, Chicago:

The Thyrotropic Hormone of the Anterior Pituitary Gland: Exhibit showing (1) chemical characteristics and methods of preparing solutions; (2) method of assay by graphic analysis of hyperplasia of thyroid of test animals; (3) physiologic effects in animals; (4) bio-assay in man of occurrence of thyrotropic hormone in blood and urine, and (5) effects of injection in man.

C. E. ERVIN and H. F. HUNT, Geisinger Memorial Hospital, Danville, Pa.:

Diagnosis and Treatment of Undulant Fever: Exhibit illustrating the incidence, methods of diagnosis, symptoms and treatment of undulant fever; temperature curves of a number

of typical and atypical cases that were treated by means of the intravenous injection of killed typhoid and paratyphoid bacilli; various laboratory procedures utilized in the diagnosis of this disease.

FRANK W. HARTMAN, Henry Ford Hospital, Detroit:

Oxygen Therapy with the Use of Liquid Oxygen and Air; a New Efficient Low-Cost Oxygen Tent: Exhibit showing an apparatus that uses only liquid gases (liquid air and liquid oxygen) to supply the oxygen and the cooling; the machine is small and goes over the head of the bed, and a transparent canopy of the new transparent rubber is used; no pressure tanks and no reducing valves or flow meters are necessary.

WALTMAN WALTERS, JOHN M. MCGOWAN, WINFIELD L. BUTSCH, NORMAN W. THIESSEN and PAUL A. KNEPPER, Mayo Clinic, Rochester, Minn.:

Pathologic Physiology of the Common Bile Duct and Its Relation to Biliary Disease; the Sphincter of Oddi, Its Relation to Biliary Colic; Biliary Obstruction: Exhibit of transparencies showing persisting obstructions of the common bile duct subsequent to surgical procedures, consisting of pancreatic obstructions of the common bile duct with and without reflux into the duct of Wirsung, and spasm or inflammation of the sphincter of Oddi; transparencies of kymographic tracings showing the variation in pressure within the common bile duct during biliary colic are shown; demonstrations of spasms of the sphincter of Oddi with increase in intraductal pressure and filling of the common and hepatic ducts, particularly the finer hepatic biliary radicles during the pain and at the height of the increase of the sphincter of Oddi are demonstrated to follow the use of amyl nitrite and glyceryl trinitrate, whereas morphine causes spasm of the sphincter and increase in the intraductal pressure; motion picture showing method of studying intraductal pressure; transparencies of the duodenum injected with barium and of the common bile duct injected with brominol to show the effect of morphine and amyl nitrite on the duodenum and the lower end of the common bile duct. A kymographic tracing to show increase in duodenal motility following administration of morphine.

Section on Pathology and Physiology

T. A. GONZALES and JACOB WERNE, Office of the Chief Medical Examiner, New York:

Lesions in Sudden Death: Exhibit comprising a statistical and illustrated review of the lesions encountered in persons dying suddenly of other than violent causes; specimens, photographs and drawings of the gross and microscopic lesions, and charts. The subject is considered according to the body system involved in the failure that led to the sudden death; particular attention is paid to coronary insufficiency without demonstrable recent occlusion and to the so-called status thymicolymphaticus.

JOSEPH F. HAMILTON, Dr. Willis C. Campbell Clinic, Memphis, Tenn.:

Pseudomycosis—Indolent Ulcer: Exhibit of photographs showing lesions before and after treatment.

J. GARRETT HICKEY and M. J. OPPENHEIMER, Temple University Medical School, Philadelphia:

Circulation Schema; Illustration of Normal and Pathologic Hemodynamics: Exhibit of motor-driven cam and adjustable lever with friction cones for speed changes (from forty to seventy-two per minute) rhythmically compressing a bulb (ventricle) connected with a bottle (atrium); valves, (mitral and aortic) with stopcocks and by-passes for stenoses and insufficiencies are interposed; small tubing (arterial system) leads to a glass wool filled U tube (capillaries) with a return system, (veins) to the bottle; proximal to the capillary area is a clamp, (arterioles); manometers (arterial and venous) are used for kymograph recording.

ISAAC SCHOUR, University of Illinois, Chicago:

Tooth-Ring Analysis: Exhibit of photomicrographs, charts and models which demonstrate the use of the incremental rings in the teeth for the analysis of biologic processes and events; (1) the neonatal ring in human deciduous teeth which records the biologic changes experienced by the new-born infant; (2) the ring pattern in the incisor of the rat with a revolving model comparing the action of this tooth of continuous growth

to the drum of a kymograph, which records the alterations in calcium metabolism accurately and promptly; (3) the ring pattern of the human incisor and its incremental mode of growth; (4) the 16 micron calcification rhythm in teeth; (5) the growth rhythm in teeth; (6) the experimental evidence which supports the concept that the growing tooth is a very delicate recorder of biologic processes.

OSCAR AUERBACH and SAMUEL LIPSTEIN, Sea View Hospital, Staten Island, N. Y.:

Pathology of Pulmonary Tuberculosis: Exhibit of mounted lung specimens, each accompanied by a photograph, short clinical history and anatomic diagnosis, showing (1) primary complex, (a) healed, (b) progressive; (2) generalization forms, (a) miliary, (b) large nodular; (3) chronic pulmonary tuberculosis, which will demonstrate all forms of early foci to extensive involvement; (4) collapse therapy, (a) pneumothorax; (b) thoracoplasty; (5) silicosis and tuberculosis.

RIGNEY D'AUNOY and EMMERICH VON HAAM, Department of Pathology, Louisiana State University Medical Center, New Orleans:

Granuloma Inguinale and Lymphogranuloma Inguinale, a Clinical and Pathologic Study: Exhibit dealing with a comparative study of the pathologic and clinical characteristics of both diseases in order to stress the important differential diagnostic factors.

LEONARD G. ROWNTREE, ARTHUR STEINBERG, N. H. EINHORN, J. H. CLARK, GEORGE M. DORRANCE and E. F. CICCONE, Philadelphia Institute for Medical Research, Laboratory of Philadelphia General Hospital and American Oncologic Hospital, Philadelphia, and A. M. HANSON, Faribault, Minn.:

Normal and Abnormal Growth: Exhibit dealing with normal and abnormal growth, showing (1) transparencies in color; (2) motion pictures; (3) lantern slides and microscopic demonstration; (4) thymus-treated rats; (5) pineal-treated rats; (6) tumor rats and other tumor animals; (7) extract of thymus, pineal and wheat germ; (8) preserved specimens; (9) frequent sacrifice of tumor animals to demonstrate malignancy.

EUGENE R. WHITMORE, Georgetown University Medical School, Washington, D. C.:

Whole Organ Sections, Gross and Microscopic: Exhibit of (a) slices of whole organs, stained to show the gross pathologic condition, mounted in museum jars, with brief clinicopathologic abstract accompanying each specimen; (b) whole organ micro sections of the same organs, stained in the usual way for micro study, mounted on lantern-slide-sized micro slides, for micro projection, as well as for study with the microscope; (c) photographs in colors of the same specimens and a microscope for study of the micro slides, both lantern slide size and regular 3 by 1 inch micro slide sections; (d) a micro projector, for projection within the booth of the lantern slide sections.

WILLIAM G. EXTON and ANTON R. ROSE, Prudential Insurance Company of America, Newark, N. J.:

Clinical Laboratory Methods: Exhibit dealing with simpler and shorter quantitative clinical pathologic methods with precision measurements which give useful information in clinical routine and research when other methods are impracticable; new sugar, fat, protein and red blood cell methods portrayed step by step and the end-materials measured in the electroscopometer by colorimetry or nephelometry with either standards or calibrations; demonstrations of different measurements, their indications, and universal application with one instrument. *Sugar Methods:* (1) qualitative and quantitative test for sugar in urine by di-sodium-di-nitro-salicylate; (2) reduction rate sugar method for indicating the nature of urinary reducing substances; (3) prevention of glycolysis in blood; (4) micro-modification of Folin-Wu blood sugar method. *Fat Methods:* (1) total lipins; (2) lecithin; (3) and (4) cholesterol, free and ester; (5) total fatty acids, and (6) neutral fat. *Protein Methods:* (1), (2) and (3) total protein in blood, urine and spinal fluid; (4), (5) and (6) albumin and globulin in blood, urine and spinal fluid; (7) fibrinogen and protein subfractions in plasma. *Red Blood Cell Methods:* (1) number or count; (2) size or volume; (3) hemoglobin content.

GEORGE J. KASTLIN, J. M. SHELTON and LESTER HOLLANDER, Pittsburgh Skin and Cancer Foundation, Pittsburgh:

A Study of Blood Cells: Exhibit of water color drawings showing the development of the blood cells from a single parent cell; water color drawings showing composite blood pictures of various diseases, including leukocytoses, leukemias and anemias; natural color transparencies of normal and abnormal blood cells; photographs taken from blood smears of patients.

M. J. SCHLESINGER, Beth Israel Hospital, Boston:

An Improved Method of Demonstrating the Coronary Artery Circulation with Evidence on the Functional Significance of Anastomoses: Exhibit of human hearts, in which the coronary arteries were injected with a radiopaque mass; each film shows all the arteries of a heart in one plane and are colored to emphasize the right and left coronaries and their anastomosis; charts and photographs illustrating the method.

HUGH JETER and WAYNE HULL, Oklahoma Hospital and University of Oklahoma Medical School, Oklahoma City:

Color Photography and Its Application in Medical Teaching: Exhibit of photographs in color representing clinical material, gross specimens, photomicrographs and reproduced color charts; colored lantern slides illustrating the practicability of using color photography in medical teaching.

VIRGIL H. MOON, DAVID R. MORGAN and MARSHALL M. LIEBER, Department of Pathology, Jefferson Medical College, Philadelphia:

Shock, Its Pathology and Sequelae: Exhibit of gross and microscopic material from human cases and from animals showing the pathologic features characteristic of shock; the sequelae of sublethal degrees of shock are similarly presented; charts indicating the etiology and mechanism of these and photomicrographs are presented.

LESTER R. DRAGSTEDT and JOHN VAN PROHASKA, Department of Surgery, University of Chicago Clinics, Chicago:

Lipocain, a New Pancreas Hormone: Exhibit showing that depancreatized animals adequately treated by diet and insulin regularly die within two to three months; extreme fatty infiltration of the liver is found in such animals but this fatty change may be corrected and life prolonged by the oral administration of a new hormone of pancreatic origin.

WILLIAM E. EHRLICH, GEORGE M. BARTOL and RICHARD E. WOLF, Department of Pathology, University of Pennsylvania School of Medicine:

Experimental Glomerular Nephritis in Rabbits: Exhibit of (1) table showing the method employed; (2) table showing the results obtained by this method; (3) microscopes showing the renal lesions produced (typical glomerular nephritis); (4) charts showing the clinical changes, as proteinuria, blood urea retention and renal anemia; (5) charts showing the results of new dye tests in these animals (with cyanol and azofuchsin); (6) apparatus and dyes used for the tests.

SAMUEL M. FEINBERG and THEODORE BERNSTEIN, Northwestern University Medical School, Chicago:

Mold Spores in Air; Causes of Asthma and Hay Fever: Exhibit of culture plates and tubes showing the fungi important in these cases; photomicrographs and drawings of some of the fungi; charts and curves showing incidence of mold spores, their "seasons"; charts showing results of tests and treatment and enlarged drawings of fields under the microscope, depicting areas on exposed slides and their content of pollens, fungus spores and other organic and inorganic matter; specimens indicating the sources of these fungi (such as grains, vegetables); the object of the exhibit is to demonstrate the finding of widespread contamination of the general atmosphere by mold spores capable of causing allergic symptoms and to illustrate that very many instances of asthma and hay fever occur as a result of allergy to this group of substances.

MAURICE ROSENTHAL and EDWIN J. GRACE, Long Island College of Medicine, Brooklyn:

Experimental Radium Poisoning: Exhibit of transparencies and photomicrographs showing the changes in lymph nodes, bone marrow and teeth of rabbits; charts describing the pathologic changes in teeth; general features of radium poison-

ing; bone marrow changes; peripheral blood changes and lymph node changes; the photographic method of detecting radium in tissues (bones); differentiation of true radium poisoning from damage due to irradiation during therapeutic use and other conditions.

Section on Nervous and Mental Diseases

JAMES W. WATTS, WALTER FREEMAN and RALPH W. BARRIS, Washington, D. C.:

Psychosurgery, the Effect on Behavior of Surgical Interruption of Pathways in the Frontal Lobe: Exhibit of diagrams, photographs and tables dealing with the indications for operation, the manner in which cases are selected, the operative technic and the results of operation. Roentgenograms of the skull showing the operative site visualized by the injection of thorium dioxide sol; observation on frontal lobe functions before and after operation. When a patient has been able to return to work, he has been observed for signs of deficits produced by the operation; when a patient has been unable to return to work, studies have been made to determine the cause; summaries of twenty-odd cases are presented. Clinical material is supported by behavior changes which follow prefrontal lobotomy in the monkey. No alteration observed after unilateral operation; following bilateral lobotomy, animals immediately lose former reactions of aggressiveness and of fear. Monkeys having the unilateral and bilateral operation are on exhibit, illustrating the striking alteration in behavior.

LEWIS J. FRIEDMAN, JOSEPH T. TRAVERS, WILLIAM ROBINSON and A. TOLK, Bellevue Hospital, New York:

Encephalographic Studies of Posttraumatic Sequelae Following Head Injuries: Exhibit dealing with sixteen cases, including short history of each case; operative observations, results and encephalographic study; some cases have both lateral and anterior posterior projections; some cases of subdural hematoma show the midline shift and compression; other cases show varying degrees of brain atrophy; many cases contain inadequate histories of trauma and in neurologic examination are found negative; one case showing air in the subdural space for differential diagnosis from brain atrophy.

TRACY J. PUTNAM, Boston City Hospital, Boston:

The Treatment of Hydrocephalus by Endoscopic Coagulation of the Choroid Plexus: Exhibit of oil paintings to illustrate the circulation of the spinal fluid and to show the method of operation with the ventriculoscope; photographs of patients before and after operation; photographs and colored transparencies of the abnormalities involved in hydrocephalus and of the scars resulting from operation; charts of the mental development of patients operated on and followed for periods up to three years; a sample of the ventriculoscope and a "mannequin" hydrocephalic brain in which its use may be practiced.

TEMPLE FAY, FRANK KONZELMANN and MICHAEL SCOTT, Temple University, Philadelphia:

Unusual Tumors of the Brain and Spinal Cord: Exhibit presenting interesting and unusual tumors of the brain and spinal cord; pathologic specimens represent some important problems in differential diagnosis of lesions of the central nervous system; encephalographic and roentgen studies as aids to diagnosis in these particular lesions are presented along with protocol of the cases; the value of the spinogram in diagnosis and localization is illustrated; the results of tentorial decompression in a series of medulloblastomas is portrayed; the exhibit contains pathologic specimen x-ray transparencies, graphs and charts.

E. A. SPIEGEL and MONA SPIEGEL-ADOLF, Temple University School of Medicine, Philadelphia; J. B. PRICE, Norristown, Pa., and N. P. SCALA, Washington, D. C.:

Physiopathology of the Sixth Sense: Exhibit illustrating the reflex activity of the labyrinth, particularly the reflexes on the eyes and the vegetative nervous system (pathogenesis of seasickness), the relation of labyrinthine impulses to the cerebral cortex (electro-encephalogram in labyrinth stimulation, vertigo in brain tumors, cortical reactions of labyrinthine origin) and methods of examination of the sense of position and of reactions during rotation.

EDWARD C. ROSENOW, Mayo Foundation, Rochester, Minn.:

The Relation of Streptococci to the Viruses of Encephalitis and Poliomyelitis: Exhibit of charts showing (1) diplococci, stained by a new method, in filtrates of the viruses; (2) lesions produced by injection of viruses derived from streptococci; (3) streptococci in the spinal fluid and in lesions of human beings having poliomyelitis and encephalitis, and in monkeys following inoculation of natural and experimentally made virus; motion pictures showing symptoms and lesions in monkeys inoculated with viruses derived from streptococci.

EBEN J. CAREY, Milwaukee:

Wave Mechanics of the Nervous Impulse: Exhibit of photomicrographs of experiments on the nervous and muscular systems; apparatus revealing pressure waves in glass rods with the aid of polarized light, which are like those in the nervous system. The nervous system of different animals was subjected to strong strychnine stimulation or depressed by prolonged anesthesia with urethane and ether. Histologic evidence of the augmentation of amplitude and increase of frequency of pressure pulses are observed when the nervous system is subjected to the prolonged action of depressant agents. In other animals the medulla oblongata was traumatized by a sudden blow. Experimental evidence demonstrates that the axons of nerve fibers are in the physical state of a colloidal liquid. By a sudden blow on the medulla the fluid pressure is transmitted through the axons of the tracts of the spinal cord. These balloon out or cause a "blow-out" at a distance from the initial site of sudden high pressure to cause acute traumatic syringomyelia.

MOTION PICTURE PROGRAM

In an area adjoining the exhibits of the section, motion pictures on nervous and mental diseases will be shown on a definite schedule throughout the week.

J. RUDOLPH JAEGER—*Neurosurgery Procedures.*

Section on Dermatology and Syphilology

NELSON PAUL ANDERSON, SAMUEL AYRES JR. and PAUL D. FOSTER, Los Angeles:

Atypical Manifestations of Scabies: Exhibit of illustrations, charts and photographs depicting various atypical manifestations of scabies, such as severe generalized pyoderms, urticaria, persistent postscabetic nodules, involvement of the face (infants), pseudochancres from penile lesions; microscopic slides showing the adult organism, ova and feces situated in a burrow, and a chart outlining a simple but effective therapy.

REUBEN FRIEDMAN, Philadelphia:

The Story of Scabies: Exhibit of photographs and photomicrographs depicting the burrow of *Acarus scabiei*, with explanatory poem.

RHODA W. BENHAM and EDWARD D. DELAMATER, New York:

The Pathogenic Fungi: Exhibit showing charts, pictures and specimens of recognized genera of the pathogenic fungi, pictures of clinical lesions caused by each genus, cultures and microscopic slides illustrating each genus; charts showing different species and variants of the dermatophytes and their relationship to the saprophytic gymno-ascaceae.

GEORGE M. LEWIS, MARY E. HOPPER and ROYAL M. MONTGOMERY, New York:

The Skin Manifestations of Trichophyton Purpureum: Exhibit consisting of charts, diagrams and photographs showing the microscopic, cultural and culture mount appearance of *Trichophyton purpureum*; the diverse skin manifestations found in patients; lesions on the interdigital webs, the soles and sides of the feet; the palms and fingers; the inner thighs, nails and occasionally on the smooth skin; a case of follicular involvement.

S. WILLIAM BECKER and HAROLD W. THATCHER, University of Chicago, Department of Medicine, Chicago:

Studies on Multiple Idiopathic Hemorrhagic Sarcoma of Kaposi: Exhibit of charts, photographs and photomicrographs,

giving historical review, nomenclature and theories relative to the nature of Kaposi's sarcoma; presentation of pathologic studies, including injection of colloidal material, inoculation and tissue culture.

FRANCIS P. MCCARTHY, JAMES C. HEALY and FRANCIS H. DALEY, Boston:

A Clinical and Pathologic Demonstration of Oral Lesions: Exhibit of lantern slides and charts showing oral lesions; special study of leukoplakia buccalis; bismuth pigmentation and stomatitis; clinical and pathologic studies; demonstration of common and rare oral lesions; manifestations of allergy in oral cavity, clinical and pathologic studies; manifestations of endocrine dysfunction in oral cavity.

M. E. OBERMAYER, Chicago:

Ammonium Succinimido-Aurate, a Gold Compound of Low Toxicity: Exhibit showing samples of various gold compounds in use in dermatology and charts depicting their chemistry; the chemistry of ammonium succinimido-aurate and tables illustrating the relative toxicity of the drugs.

THEODORE CORNBLEET, Chicago:

Excretion Activities of the Skin: Exhibit demonstrating two general methods by which the skin excretes metabolites: first, as a solution or emulsion in sweat and sebum, as for example, ketone body excretion; second (less known but equally important) as deposits occurring into the basal layer of the epithelium and reaching the surface in the ordinary evolution of the cells toward the keratin layer; these deposits are cast off with the topmost keratinized cells which house them; iodides and arsenic are excreted in this manner. There may be variations in this method of excretion, as, for instance, some persons show a delay between the ingestion of arsenic and its scaling off, this delay being instrumental in producing such changes as keratosis.

A. BENSON CANNON, New York:

Arsphenamine Therapy of Syphilis in General Practice: Exhibit setting forth a systematic and rational procedure for the treatment of syphilis in all stages; demonstration of the administration of arsphenamine by a safe and practical method available to the general practitioner; graphic presentation of a complete plan of treatment, accompanied by figures and illustrations summarizing the experience on which the plan is based.

A. J. CASSELMAN, State Department of Health, Trenton, N. J., and E. W. FLOSDORF, University of Pennsylvania, Philadelphia:

The Diagnosis of Syphilis, Darkfield Equipment, Wassermann and Flocculation Standardization, Special Model of Lyophile Apparatus: Exhibit of a darkfield outfit which shows the advantage of semipermanent adjustments of light source, mirror, microscope and centering of darkfield condenser; adjustments should be unnecessary except annually. The only efficient Wassermann or flocculation control is a weakly positive serum; liquid serum is too unstable to be used as a permanent standard; a standard serum of a single given potency, preserved in lyophilic form, can be kept under refrigeration for six months or longer without detectable change, is suitable for mailing and will permit every laboratory to determine the exact sensitivity of its methods; a generally agreed on standard strength of serum would permit the adoption of the same degree of sensitivity of every laboratory; descriptive and explanatory charts.

CHARLES R. REIN, FRED WISE and ALFRED CUKERBAUM, New York:

The Use of the Kline Finger Blood Tests in the Detection of Syphilis in Blood Donors Immediately Prior to Transfusion: Exhibit demonstrating a simple method for the detection of syphilis in all donors (professional and nonprofessional) immediately prior to transfusion; the procedure requires only a few minutes and can be done simultaneously with the blood typing and direct cross agglutination, without loss of time.

BENJAMIN S. KLINE, Mount Sinai Hospital, Cleveland:

Evaluation of Results of Flocculation Tests for Syphilis in the Recent American Conference; Outline of Studies for Standardization of These Tests: Exhibit of charts showing

results of the recent American Serological Conference with tests of blood and of spinal fluid arranged (1) in order of specificity and (2) in order of sensitivity; charts giving outline of studies to standardize flocculation tests for syphilis (1) list of studies, (2) antigen free of adventitious substances, (3) preparation of optimal antigen emulsions, (4) determination of optimal test conditions.

Section on Preventive and Industrial Medicine and Public Health

CHARLES GOODMAN, New York:

Etiology of Thrombo-Angiitis Obliterans: A Diagnostic Skin Test for Thrombo-Angiitis Obliterans and Typhus Fever: Exhibit of statistical charts, photographs, lantern slides and microscopic slides demonstrating a new conception of the etiology of thrombo-angiitis obliterans and the development of a diagnostic skin test for thrombo-angiitis obliterans and typhus fever; results observed in a study of more than 600 tests showing the relationship between the two, proving that the skin tests will prove positive in the active stage as well as in convalescent and recovered typhus, even after a period of fourteen or fifteen years; results obtained after using several different strains of *Rickettsia prowazeki* from various sources; similar tests have proved negative in a large number of controls, including presumably normals, arteriosclerosis with and without gangrene, diabetes with and without gangrene, typhoid, tuberculosis, pneumonia and other acute infectious diseases.

W. AMBROSE MCGEE, Richmond, Va.:

The Relative Value of Schilling Differential Counts, Sedimentation Rates and Lymphocyte-Monocyte Ratios in Tuberculosis of Childhood: Exhibit of charts showing laboratory observations in various stages of childhood tuberculosis, a comparison of those procedures and their relative value from a diagnostic and prognostic point of view.

LLOYD ARNOLD and IRWIN G. SPIESMAN, University of Illinois College of Medicine, Chicago:

Susceptibility to Common Colds: Exhibit of charts and graphs showing results of temperature studies of nasal mucosa under various environmental conditions; the influence of hydrotherapy, diet and mental hygiene in prevention of colds is illustrated in various ways.

FRED J. HODGES, JOHN C. BUGHER and H. M. POLLARD, University of Michigan Hospital, Ann Arbor, Mich.:

The Use of Machine Methods in the Indexing of Medical Information; Statistical Information; Cancer Case Records: Exhibit of mechanical tabulating machines consisting of a card punch, a verifier, a reproducing punch, a card sorter and a tabulating and listing machine; the actual procedure of recording roentgenologic observations on punch cards will be demonstrated by attendants showing every step from the examination of films to the filing of completed punch cards; the approach to previously recorded information of this sort will also be shown as well as the facility with which such information can be analyzed and prepared for statistical treatment; a new and unique plan of using these facilities for accumulating accurate and pertinent information on all cancer cases will also be shown.

S. E. GOULD and I. F. HUDDLESON, Eloise and East Lansing, Mich.:

Undulant Fever (Brucellosis): Exhibit illustrating etiology, methods of diagnosis and treatment by means of models, transparencies, charts; motion picture portraying the geographic distribution, clinical manifestations, diagnosis and treatment of the disease; the rôle of domestic animals that are usually unrecognized as sources of infection; the methods of performing the skin test, the rapid slide test and the opsonic test; the method and results of the use of brucellin, a filtrate of brucella.

J. W. SCHERESCHESKY, United States Public Health Service and Harvard Medical School, Boston:

Carcinogenic Compounds and Lung Tumors in Mice: Exhibit of charts showing the structural formulas of various pure carcinogenic compounds; samples of the compounds, specimens in Kaiserling's solution showing tumors induced; photomicrographs of typical tumors; lung tumors in mice; pathologic

specimens of mice in Kaiserling's solution showing induction of lung tumors by carcinogenic compounds implanted subcutaneously; charts showing hereditary transmission of susceptibility to lung tumors in mice as a dominant factor; photomicrographs of lung tumors.

HENRY H. KESSLER, Newark, N. J.:

Cineplastic Amputation: Exhibit of photographs, plaster models, sample of prosthesis and motion pictures demonstrating the utility of the cineplastic prosthesis for those who have lost an arm in industrial and public accidents.

F. HOWARD WESTCOTT, FRED W. GRAEF, HAROLD E. CLARK, JAMES J. SHORT and ABBOTT W. ALLEN, New York:

Medical Survey: Exhibit showing a study of hospital records concerning illnesses and accidents that have occurred among 3,000 employees: the group that received preemployment examination compared to the group that was employed before a medical department was established to which no preemployment examination was given; the cause of lost time for each system is graphically arranged.

RAPHAEL POMERANZ, Newark, N. J.:

Silicosis in Pulverizing Plants: Exhibit of transparencies of dust, serial roentgenograms, gross specimens and photomicrographs demonstrating anthracosis and silicosis, silicosis and tuberculosis, experimental work with the same type of silica dust, differential diagnosis, cancer and silicosis and some methods of prevention.

A. J. LANZA, W. J. MCCONNELL and J. W. FEHNEL, Metropolitan Life Insurance Company, New York:

Industrial Hygiene Survey: Its Scope and Method: Exhibits of charts and photographs presenting a graphic description of mechanics and process of determining health hazards in industry.

HENRY C. SWEANY, Municipal Tuberculosis Sanitarium, Chicago:

The Chemistry and Pathology of Pneumoconiosis: Exhibit of specimens, roentgenograms, charts and photomicrographs of human specimens representing the principal varieties of pneumoconiosis; demonstrations on the chemical methods used with the various steps in chemical analysis; demonstration of polarizing microscope and its limitations.

W. F. WELLS and MILDRED WEEKS WELLS, Harvard School of Public Health, Boston:

Air-Borne Infection: Exhibit showing the methods of bacterial analysis of air by which air-borne infection has been demonstrated, and the application of ultraviolet rays to the sanitary control of air-borne infection, with special reference to hospital practice.

DERYL HART, Duke Hospital, Durham, N. C.:

Sterilization of the Air in the Operating Room with Bactericidal Radiant Energy: Exhibit of charts of cultures of the air, of all supplies, and of noses and throats showing that air is the greatest source of wound contamination; photographs showing the extensive destruction of all types of bacteria at distances of from 5 to 10 feet from the source of radiation within one to thirty minutes of exposure; photographs and charts showing the presence of bacteria in the air of hospitals in at least sixteen states, some being air conditioned and others not; charts showing the great reduction in number of infected wounds and reduction in postoperative temperature and duration; photographs showing effects of ultraviolet radiation on wound healing in experimental work of animals; charts showing the physical characteristics of radiation and its intensity and bactericidal efficiency at various points in the operating room.

F. H. FALLS, R. R. FERGUSON, MAURICE L. BLATT, Chicago, FRANK J. JIRKA and GRACE S. WIGHTMAN, Springfield, Ill.:

Illinois State Program for Educational Courses in Maternal and Infant Welfare: Exhibit of charts showing co-relation of various organizations cooperating in the development of this plan of education; poster drawings showing home delivery set-up for normal labor and for operative delivery; outlines of typical lectures on two obstetrical and one pediatric subject,

illustrated by original drawings from which teaching lantern slides are made, covering the subjects of puerperal sepsis, obstetrical hemorrhages and contagious diseases; statistical charts on maternal and infant mortality, comparing mortality in state and counties with that of the United States, and showing the chief causes of maternal death; educational program comprising refresher courses in pediatrics and obstetrics; manikin demonstration course; dry clinics and consultations in local hospitals; small courses, one week intensive work; development of county committees on maternal welfare.

Section on Urology

ROGER W. BARNES, Los Angeles:

The Teaching of Urology to Undergraduates: Exhibit of models of normal and pathologic conditions of the prostate as palpated by rectum; with these will be grouped coexisting condition such as specimens of tuberculous kidney or pyelograms, with the tuberculous prostate; roentgenograms and specimens of prostatic calculi; specimens of upper urinary tract dilatation due to back pressure from prostatic hypertrophy; roentgenograms of metastasis from carcinoma of prostate.

JAMES J. JOELSON and EUGENE FREEDMAN, University Hospitals, Cleveland:

Urologic Roentgenology: Exhibit of pyelograms and other films of the urinary tract demonstrating the changes which occur in the various urologic diseases.

H. DABNEY KERR and CARL L. GILLIES, University Hospital, Iowa City:

Roentgen Diagnosis of Lesions of the Lower Urinary Tract: Exhibit showing the value of opaque and air cystograms in the diagnosis of vesical lesions and of cysto-urethrograms in prostatic and urethral lesions; demonstration of bladder tumors, nonopaque stones, diverticula, benign and malignant prostatic lesions, urethral stricture, and so on.

WILLIAM J. EZICKSON and JACOB B. FELDMAN, Philadelphia:

Vitamin A Deficiency in Individuals with Urinary Lithiasis: Exhibit of charted graphs of the dark adaptation examinations of each individual reported in the study, showing condition before treatment and after treatment; prints made from roentgenograms depicting the clinical story of each case relative to urinary calculi, also several charts giving the analysis of the study of vitamin A deficiency of this group of cases.

ALEXANDER RANDALL, Department of Urology, University of Pennsylvania and Abington Memorial Hospital, Philadelphia:

Origin and Growth of Renal Calculi: Exhibit of primary renal calculi in postmortem studies on human kidneys demonstrating their origin from lesions of the renal papilla.

NELSE F. OCKERBLAD and H. E. CARLSON, Kansas City, Mo.:

The Distribution of Ureteral Pain: Exhibit dealing with studies of the distribution of ureteral pain in man by applying a small electrical stimulus to the ureter by means of a specially constructed catheter electrode; the patient regularly designated definite areas to which the pain was referred, and the distribution of pain of the entire ureter was mapped out in this manner.

W. CALHOUN STIRLING and A. M. LANDS, Washington, D. C.:

An Experimental and Clinical Study of Traumatic Kidney Injuries: Exhibit of plates, photomicrographs and drawings representing an experimental study of a series of experiments on animals with careful controls used in each group of experiments. New facts are listed in the relation between anemia and kidney trauma; a marked depression of the hematopoietic system is shown as a result of some toxemia liberated by the injured kidney; the technic of kidney repair is illustrated.

R. H. FLOCKS, Department of Urology, State University of Iowa, College of Medicine, Iowa City:

The Arterial Distribution Within the Prostate Gland—Its Role in Prostatic Resection: Exhibit of (1) photographs and diagrams of bladder necks and prostate glands in which the arteries have been injected to illustrate their distribution in the normal adult prostate, the infant prostate, and the enlarged prostate both before and after resection; (2) specimens illustrating typical configurations in which the arteries have been injected with barium and then cleared by the Speltcholtz

technic so that the vessels can be clearly seen; (3) stereoscopic photographs of these specimens illustrating the arterial distribution within the prostate at various ages and the significance of this distribution in relation to surgery on the prostate gland.

Section on Orthopedic Surgery

DAVID M. BOSWORTH, A. SUMNER PRICE and B. M. BOSWORTH, New York:

Lesions and Surgery of the Menisci of the Knee: Exhibit of actual specimens, transparencies of photographs, roentgenograms and drawings, photographic enlargements of specimens and photomicrographs in addition to a motion picture in color of operative procedure and lesions found.

GEORGE E. BENNETT, Children's Hospital School, Baltimore:

Orthopedic Appliances and Demonstration of Examination, Protection and Treatment in the After-Care of Anterior Poliomyelitis Cases: Exhibit of orthopedic appliances and motion picture demonstration of examination, protection and treatment in the after-care of anterior poliomyelitis cases; (1) emphasizing the principles and neutral rest position for protection of all muscles in poliomyelitis cases; (2) examination of leg muscles; (3) examination of arm and abdominal muscles; (4) detailed protection for isolated muscle groups; (5) treatment, types and principles involved; casts, braces, splints, frames, muscle charts and improved passive vascular exercise boot and cuffs.

CHARLES S. VENABLE, WALTER G. STUCK and ASA BEACH, San Antonio, Texas:

Electrolysis the Determining Factor in Osteosynthesis with Metals: Exhibit showing experiments in which different metals and alloys were used in various combinations, followed by macroscopic, microscopic, x-ray and biochemical examinations; biochemical examination showing the transference of ions of one metal to the other, according to the laws of electromotive force of metals, showing that electrolysis is the controlling factor and that a metal entirely resistant to body fluids, acting as the electrolyte, must be used for consistent success in metallic-osteosynthesis.

JAMES A. DICKSON, Cleveland Clinic, Cleveland:

Torticollis: Experimental and Clinical Studies: Exhibit of photomicrographs showing the similarity of the pathologic changes in (1) torticollis, (2) ischemic paralysis, and (3) changes produced experimentally by obstructing the venous supply while the arterial supply is left intact; photographs showing the patients before and after operation; overcorrection maintained by sandbag immobilization only.

SIGMUND ERSTEIN, New York:

The Crutch in Art Through Forty Centuries: Exhibit of prints of the masterpieces of art dating from 2830 B. C. to the present, tracing the use of the staff, the crutch and other appliances, by the handicapped of forgotten ages.

BADLEY L. COLEY and NORMAN L. HIGINBOTHAM, New York:

Primary Tumors of Bone: Three horizontal rows of framed transparencies, each row to occupy approximately a 25-foot length; grouped to illustrate the history, clinical, roentgenographic, pathologic and therapeutic aspects of the different types of bone tumors as observed at the Memorial Hospital and the Hospital for Ruptured and Crippled, New York.

FRED H. ALBEE and ROBERT L. PRESTON, New York:

The Mechanism of Joint Control by Muscular Action: Exhibit of drawings, diagrams and skeletal models demonstrating how active control of certain joints can be brought about by the surrounding muscles even though they have been weakened by trauma or disease and how to restore the mechanical bone lever when bony contours have been changed, the restoration of active muscle control to the hip when this control is entirely absent as in ununited fracture, infantile paralysis, loss of the lever at the top of the femur from old tuberculosis or following arthroplastic operation to produce motion, the stabilizing effect on a surgically made elbow joint of elongating the olecranon process as a lever.

L. D. SMITH, Milwaukee, Wis.:

Reduction and Fixation of Shaft Fractures by Skewers: Exhibit of an apparatus with skewers fixed in a fractured femur, showing the method of manipulation of the fragments by skewers, and films of shaft fractures illustrating their reduction and fixation.

J. DEWEY BISGARD, Omaha:

Giant Cell Tumor and Cartilaginous Exostoses Experimentally Produced in Animals: Exhibit showing a series of immature rabbits from each of which a segment of the radius was removed; in most of these, partial or complete separation of the distal ulnar epiphyses developed unexpectedly, and these reduced completely or nearly completely spontaneously; in some there developed at the point of separation on the diaphyses lesions that were grossly and microscopically typical cartilaginous exostoses; in two animals there developed also tumors that grossly and microscopically were giant cell tumors. The development of these tumors is shown in roentgenograms and photomicrographs.

EARL D. MCBRIDE and ELIAS MARGO, Oklahoma City:

Scoliosis: A New Derotation Apparatus for Treatment of Ambulatory Cases and New X-Ray Method of Recording: Exhibit showing a new manner of recording the skeletal deformity with an apparatus for the correction of scoliosis.

M. S. HENDERSON, H. W. MEYERDING, R. K. GHORMLEY and H. B. MACEY, Mayo Clinic, Rochester, Minn.:

Fractures, a Potential Source of Deformity and Disability: Exhibit showing: I. Methods of internal fixation for fractures of the neck of the femur with: (a) Smith-Petersen cannulated nail, (b) cannulated metal lag screw inserted over guide wire. II. Mechanical principles of reduction and fixation; roentgenograms taken before, during and at the completion of the operation show the technic and end results. III. Technic of fibular bone graft for ununited fractures of the neck of the femur is shown by skeletal models, roentgenograms and models of the operative procedures. IV. Skeletal models and postoperative roentgenograms show three types of reconstruction operation for the ununited fracture of the neck of the femur: (a) Brackett operation, (b) Whitman operation, (c) Colonna operation. V. Massive bone graft for ununited fracture of the shaft of the femur and ununited fractures of the shaft of the humerus. VI. Reversible bone grafts for fracture of the shaft of the tibia are shown by similar means. VII. Malunited fractures near the joints. VIII. Pathologic fractures of various types illustrated by roentgenograms. IX. Volkmann's ischemic contracture of forearm and hand. This is a common complication of supracondylar fracture of the humerus. Diagrammatic model shows displacement of fragments with deep hemorrhage, causing intrinsic pressure and blocking circulation. The early conservative treatment and late surgical treatment.

MOTION PICTURE PROGRAM

In an area adjoining the exhibits of the section, motion pictures on orthopedic surgery will be shown on a definite schedule throughout the week.

PAUL COLONNA—*Reconstruction Operation of Fracture of the Hip.*

PAUL D. HARMON and EDWARD L. COMPERE—*Reconstructive Surgery in Poliomyelitis.*

H. THEODORE SIMON—*Fractures of the Upper Extremity.*

WILLIS C. CAMPBELL—*Animated Cartoon Showing Repair of the Lateral and Anterior Crucial Ligaments of the Knee.*

Section on Gastro-Enterology and Proctology

MALCOLM R. HILL and CYRIL B. COURVILLE, Los Angeles:

Fecal Dysfunction Following Abdominoperineal Resection of the Rectum: Exhibit displaying (1) cystograms of case records; (2) artists' drawings of anatomic relationship, with special consideration as to nerve supply of the parts and probable site of injury resulting from operative procedure; (3) chart of case compilation; (4) lantern slides in color illustrating stages of operation.

GEORGE E. BINKLEY, New York:

Tumors of the Rectum and Colon: Exhibit of transparencies (1) gross tumors and microscopic sections of various types of tumors; (2) metastatic lesions to various parts of the body; (3) radiation therapy employing (a) external applications of roentgen and radium rays, (b) interstitial applications of gold filtered radon seeds, and (c) special surface rectal applicators; (4) snare removal and fulguration of rectal polyps; (5) surgery, illustrating different forms of technic for radical removal of colon and rectal cancer; (6) a small number of gross specimens and wax models.

MORRIS A. HERSHENSON, Pittsburgh:

Roentgen Exploration of the Gastro-Intestinal Mucosal Topography: Exhibit of roentgenographic transparencies illustrating the increase in diagnostic information obtained from a study of the mucosal topography of the gastro-intestinal tract; the normal and some of the more common abnormal conditions of the digestive tract are shown; the roentgenographic signs of lesions in the mucosa are compared by pictures made with and without compression; an original compression device is used and its application illustrated by photographs and by film-slide projection.

BENJAMIN HASKELL, Philadelphia:

Proctoscopic Views of Lesions of the Rectum and Sigmoid: Exhibit of specially arranged cases with tubes simulating the ordinary proctoscope in which are colored pictures approximating in size the actual lesion so that, when viewed through the tubes, they resemble the conditions found on proctoscopic examination; charts with brief descriptive notes of the lesions pictured will be placed on the walls.

WILLIAM Z. FRADKIN, Brooklyn:

Routine Study of the Diarrheas: Exhibit showing (1) apparatus used at bedside, including microscope, warm stage, sigmoidoscopes, aspirators, culture mediums and stains; (2) pathologic specimens; (3) charts illustrating the various possible etiologic factors in cases of diarrheas; (4) attempt at the etiologic classification of the diarrheas; (5) charts and models illustrating the aspiration of exudate from lesions in the sigmoid and rectum; (6) charts of bacteriologic and serologic observations in 100 cases of diarrhea; (7) value of blood agglutination tests in diarrhea; (8) practical application of bacteriophage in selected cases of diarrhea; (9) motion picture demonstration.

MAURICE FELDMAN, SAMUEL MORRISON, JOHN C. KRANTZ JR. and C. JELLEFF CARR, Baltimore:

Studies in pH of Bile and Gallstones: Exhibit of charts illustrating (1) effects of bile on stones, (2) changes in the pH variations in the different species of animals, (3) the effect on the pH of bile in the fistulous animals, and (4) the effect of drugs and diet and its effect on the pH of bile.

J. RUSSELL VERBRYCKE JR., Washington, D. C.:

Gallbladder Facts and Aphorisms: Exhibit of charts on diagnosis and treatment of gallbladder disease; analysis of a series with operative mortality in all cases of 1.95 per cent; acute cases with mortality of 4.6 per cent.

PORTER P. VINSON and EMANUEL U. WALLENSTEIN, Richmond, Va.:

The Differential Diagnosis and Treatment of Esophageal Diseases: Exhibit of drawings, photographs and x-ray films showing the different types of lesions encountered in the esophagus, with descriptions summarized under the headings of symptoms, diagnosis and differential diagnosis, treatment and results of treatment.

M. R. McQUIGGAN, Detroit:

Ulcerative Colitis—An Analysis of Forty Cases Treated According to the Method of Bergen: Exhibit showing (1) etiology, (2) pathology, (3) clinical and laboratory observations, and (4) treatment with Bergen's antiserum and vaccine prepared according to the method of Bergen.

BURRILL B. CROHN, A. A. BERG and A. PENNER, New York:

Rightsided Colitis: Life History and Surgical Treatment: Exhibit showing the usual type of nonspecific ulcerative colitis,

which begins on the left side of the colon, that is, rectum and sigmoid, a less common form that begins in the cecum or about the hepatic flexure, extending distally in the course of months or years, rarely resolving, following a downward course and completely disabling the patient. Resection in two stages is usually completely successful with a very low mortality: first stage: ileo-sigmoidostomy exteriorization of the upper cut end of sigmoid as colostomy; second stage: after six months of drainage, rightsided colectomy.

JEROME M. LYNCH, G. JOHNSON HAMILTON and EDWARD M. LEVY, The Lynch Clinic, Polyclinic Hospital, New York:

Stages in the Development of Adenocarcinoma of the Lower Bowel Together with an Anatomically Planned Operation for Their Eradication: Exhibit of photomicrographs, drawings, transparencies and gross specimens, showing how the operation for the eradication of adenocarcinoma of the lower part of the intestine removes sufficient disease condition to avoid death and yet spares enough bowel to render life worth while.

E. E. WOLDMAN and V. C. ROWLAND, Cleveland:

Peptic Ulcer Treatment by Continuous Aluminum Hydroxide Drip: Exhibit consisting of a gravity drip apparatus from a container of aluminum hydroxide suspension, through a Levin tube into a blown glass artificial stomach representing the patient; into the stomach is also dripped diluted hydrochloric acid with an indicator showing the continuous neutralization of acidity as carried out twenty-four hours a day by this method in peptic ulcer; roentgenograms before and after treatment and a group of charts summarizing the method, diets used, the properties of aluminum hydroxide and the results obtained; a new collapsible tube, nonirritating to the nose and throat and useful in preventing reflux of gastric contents.

HORACE W. SOPER, St. Louis:

Clinical Gastro-Enterology: Exhibit of charts showing a clinical summary and types of treatment in peptic ulcer diverticulosis of the colon; lesions of the small intestine; colon spasm; indicanuria, flagellate infections of the human digestive tract; cardiospasm; amebic dysentery; diathermy of the rectum and pelvic colon; ulcerative colitis; agar-agar; the oil enema, and biliary drainage.

J. L. BOLLMAN and L. K. STALKER, Mayo Clinic, Rochester, Minn:

Experimental Peptic Ulcers Produced by Cinchophen: Exhibit of wax casts of gross specimens and photomicrographs showing (a) preliminary gastritis and the subsequent development of chronic gastric ulcer; (b) stages of healing of the ulcer after discontinuance of cinchophen; (c) physiologic factors involved in the causation of the ulcer; (d) results of several methods of treatment applied to cinchophen ulcers.

I. R. JANKELSON and HENRY BAKER, Boston:

Infra-Red Photography of the Abdominal Wall in Cirrhosis of the Liver: Exhibit of photographs and infra-red pictures of the abdominal wall in health and in cases of cirrhosis of the liver; visualization of the venous network of the abdominal wall; normal and illustrative cases of the abdominal network of veins in cirrhosis of the liver; illustrative cases of pregnancy and other abdominal and pelvic diseases.

HENRY A. RAFSKY, Lenox Hill Hospital, New York:

The Nonsurgical Treatment of Pyloric Obstruction Resulting from Peptic Ulcer: Exhibit showing observations on patients suffering from pyloric obstruction resulting from peptic ulcer and treated by nonsurgical measures for a period ranging from three to ten years; follow-up results of this study are reported; the nonsurgical measures, including the method to facilitate the passage of a duodenal tube through an occluded pylorus, are described; the clinical significance of inflammatory and cicatricial pyloric obstruction both from the medical and the surgical standpoint as well as the importance of gastric decompression as a preliminary procedure before operative intervention is illustrated; the danger of alkalosis in the treatment of patients is emphasized.

MARTIN E. REHFUSS, Philadelphia:

Gastrophotography, a New Instrument with Improvements: Exhibit showing gastrophotography as done with a new

improved camera; actual photographs of the interior of the stomach, roentgenograms of these cases, abstracts of history and charts with complete description of surgical and pathologic changes.

ELMER L. EGGLESTON, GEORGE W. SLAGLE and BRUCE WHYTE, Battle Creek Sanitarium, Battle Creek, Mich.:

Behavior of Gastro-Intestinal Tract in States of Autonomic Imbalance: Exhibit showing photographic reproductions of serial gastro-intestinal films illustrating types of behavior under different degrees of imbalance and types of imbalance; charts showing signs, symptoms and physical observations, and graphs and summaries correlating roentgenologic and clinical studies.

Section on Radiology

ROBERT H. MILLWEE, Dallas, Texas:

Roentgen Slit Scanoigraphy: Exhibit of roentgenograms made through a slit while the tube was moving over the part, so that distortion in one direction is eliminated, and thereby showing the exact length of bones, or width of bones, or joint spaces; roentgenograms of hearts recording heart movement and the relative filling and emptying of ventricles and auricles in normal and diseased hearts; roentgenograms showing actual measurements of pelvic dimensions and the actual size of fetal heads; also, roentgenograms revealing change of radiographic density of tissues during physiologic changes, as in the contraction of muscles, and variation in density due to changes in distribution of the blood caused by respiration.

JAMES F. KELLY and D. ARNOLD DOWELL, Creighton University, Omaha:

The Treatment of Gas Gangrene with Roentgen Rays: Exhibit of case reports and their analysis supported by temperature charts, x-ray films and other evidence; variations in types of cases and variations in technique and the results; graphs and charts showing final conclusions.

EUGENE V. POWELL, Temple, Texas:

Roentgen Therapy of Pneumonias: Exhibit of reproductions of films showing the results obtained in cases of pneumonia in which roentgen therapy has been administered, together with a brief of their clinical history showing the course of the disease.

R. MANGES SMITH, Philadelphia:

Roentgen Treatment of Infections: Exhibit describing methods of treatment of various types of infections and illustrating the lesions before treatment as well as the results obtained; photographs before and after treatment, roentgenograms of lesions before and after treatment, temperature charts and case histories; all types of infections are included, including pneumonia, infection resulting from human bite, furuncles, carbuncles, infections about the lip and face, and sinus infection.

CLAUDE MOORE, Washington, D. C.:

The Teaching of Radiology in the Medical Schools: Exhibit of charts showing information concerning the teaching of radiology in medical schools of the United States. These charts will include the number of medical schools having an organized radiologic department, with the number and rank of men on the faculty of this department, and the number of hours devoted to teaching. Charts will show the medical schools having definite teaching connections with hospitals approved by the American Medical Association for a residency in radiology.

RICHARD SCHATZKI, Massachusetts General Hospital, Boston:

Roentgen Studies of the Inner Relief of the Gastro-Intestinal Tract: Exhibit demonstrating the value of a systematic study of the inner relief of the gastro-intestinal tract; the appearance of the inner relief in normal and in various pathologic conditions is shown, stress being laid on the diagnostic as well as differential diagnostic importance of the visualization of the inner surface of the gastro-intestinal tract.

RICHARD DRESSER, JOHN TRUMP and ROBERT VAN DER GRAFF, Massachusetts Institute of Technology, Boston:

One Million Volt Roentgen Ray Generator: Exhibit of a small model of the generator which will develop about 200 k.v.

C. F. CRAIN, J. M. SLOAN and E. F. STROUD, Corpus Christi, Texas:

Roentgen Treatment in Mastoiditis: Exhibit dealing with the x-ray diagnosis of infant mastoiditis; representative cases of infant and adult type mastoiditis treated by roentgen rays; general summary and statistical data of all cases of mastoiditis treated with roentgen rays by the authors.

GEORGE T. PACK and WILLIAM O. WUESTER, Memorial Hospital for Cancer and Allied Diseases, New York:

The Treatment of Epitheliomas of the Trunk and Extremities: Exhibit of photographs, moulages, charts, special radiation equipment and devices for application of radium and pathologic specimens showing the results of a study of epitheliomas of the trunk and the extremities.

EDITH H. QUIMBY, WILLIAM S. MACCOMB and L. D. MARINELLI, Memorial Hospital, New York:

Skin Dosage and Skin Recovery in Roentgen Therapy: Exhibit of charts showing (1) a correct method for measurement of backward scattered radiation, with data for its values, showing variation with area of field, depth of underlying tissue, and quality of radiation; the total skin dose is the sum of the direct and backward scattered radiation; (2) the effect of skin recovery on the accumulation of radiation effect; data for the calculation of the cumulative skin dose under various schemes of roentgen therapy in current use. For proper consideration of skin dosage it is necessary to take into account both sets of factors.

LEE A. HADLEY, Syracuse University College of Medicine, Syracuse, N. Y.:

Pathology of Cervical Spine: Exhibit of dissections, dried specimens, roentgenograms and microscopic sections from the cervical spine, showing pathologic conditions of the cervical spine, with special attention given to encroachment of the intervertebral foramina.

C. R. ORR, GEORGE D. POPOFF, RAYMOND S. ROSEDALE and B. R. STEPHENSON, Buffalo City Hospital, Buffalo:

Dangers of Thorium Dioxide Sol; Animal Experimentations: Exhibit of roentgenograms of gross material, photomicrographs, shadowgrams, histoshadowgrams, spinthariscopic demonstration and other data from experiments, proving that in rabbits thorium dioxide sol is a harmful substance, causing hepatic necrosis, hepatic cirrhosis, reticulo-endothelial blockade and splenic necrosis; demonstration that thorium dioxide sol is permanently stored in animal tissues; evidence that thorium dioxide sol is a definitely radioactive substance even after being immobilized in living tissues for two years. Because of these facts, it is suggested that the use of thorium dioxide sol be discontinued.

J. C. KENNING and J. E. LOFSTROM, Detroit:

Elimination of Intestinal Gas Shadows in Radiography: Exhibit of films and charts showing the effect of pitressin on the barium filled small bowel and colon as well as roentgenograms taken of the abdomen before and after the use of the drug, showing its efficacy in eliminating normal and abnormal collections of gas that may cause confusion or error.

A. O. HAMPTON, WILLIAM JASON MIXTER, J. MAURICE ROBINSON and JOSEPH S. BARR, Massachusetts General Hospital, Boston:

Rupture of the Intervertebral Disk into the Spinal Canal (Particular Reference to Lesions Causing Sciatica and Low Back Pain): Exhibit dealing with cases of rupture of the intervertebral disk into the lumbar spinal canal in which operation has been done at the Massachusetts General Hospital. These clinically important ruptures of the intervertebral disk have produced symptoms of cauda equina tumor, low back strain, sciatica and sacro-iliac disease; the cases have been studied from the anatomic, orthopedic, neurosurgical and roentgenologic points of view; the method of diagnosis by means of roentgen examination after the subarachnoid injection of iodized oil, the clinical indications for the examination and the surgical and orthopedic treatment of these cases are illustrated in detail.

SYMPOSIUM ON HEART DISEASE

The exhibit symposium on heart disease is presented by the Committee on Scientific Exhibit with the cooperation of the American Heart Association.

BURTON E. HAMILTON and K. JEFFERSON THOMPSON, Boston:

Heart Disease in Pregnant Women: Exhibit of charts showing changes in blood volume, circulation time, vital capacity, and so on; x-ray studies showing variation in heart size and shape during pregnancy; variations in distribution and size of subcutaneous veins during and after pregnancy and lactation shown by infra-red photographs; (1) in normal patients, (2) in patients with serious heart disease, (a) with no failure, (b) in congestive heart failure. Classification of heart diseases in pregnancy and maternal death rates, incidence of heart failure by months during death rate, causes of these variations and effect of treatment (prevention of approximately 75 per cent of the fatalities).

HOWARD F. ROOT, Boston:

The Heart in Diabetes: Exhibit of (1) placards with data indicating increasing frequency of cardiac complications (especially coronary disease) in diabetes; (2) electrocardiographic data concerning cardiac effects of hypoglycemia, electrocardiograms in complications; (3) treatment of coronary thrombosis with diet and insulin; (4) pathologic specimens.

P. A. O'LEARY and F. A. WILLIUS, Mayo Clinic, Rochester, Minn.:

Cardiovascular Syphilis: Exhibit of schematic drawings demonstrating the mechanism of the development of syphilitic cardiovascular disease; photographic illustrations of the pathology of cardiovascular syphilis and the symptoms it produces; a brief outline of treatment.

SAMUEL BROWN, Cincinnati:

Cardiovascular Syphilis: Exhibit of roentgenograms illustrating various phases of syphilis of the heart and great blood vessels; the importance of using several positions in the examination of the chest; the differential diagnosis of mediastinal lesions.

HENRY C. BAZETT, L. B. LAPLACE, J. C. SCOTT and MISS M. E. MAXFIELD, Department of Physiology, University of Pennsylvania, Philadelphia:

Estimation of Cardiac Output and Work and Their Relation to Arterial Resistance from Determinations of Blood Pressure and Vascular Elasticity: Exhibit showing apparatus for measuring pulse wave velocity and blood pressure optically on patients and demonstration of the actual method at stated times each day; records obtained on patients; calculation of cardiac output from the data together with the use of the method from measuring arteriolar resistance in hypertension and investigating the condition of the heart.

Z. T. WIRTSCHAFTER and LEONARD G. STEUER, Western Reserve University, Department of Medicine and City Hospital, Cleveland:

Pen Recorded Electrocardiograms and Phonograms: Exhibit showing the application of a portable high speed piezo-electric recorder "pen recording oscillograph" so designed that simultaneous permanent heart sounds and electrocardiographic tracings can be obtained directly on paper, thus eliminating the delay necessary for the development of film records; the records are comparable to those obtained by previous methods; the apparatus utilizes the piezo-electric properties of Rochelle salt for sound pickup and operating the pen of the recorder.

LOUIS GROSS, Mount Sinai Hospital, New York:

Experimental Studies on the Blood Supply to the Heart in Relation to Coronary Occlusion: Exhibit of charts, models, drawings, photographs and roentgenograms illustrating mechanisms by which the heart compensates for coronary narrowing; results of experimental attempts to enrich the myocardial vascular nutrition; results of physiologic studies on experimental coronary occlusion under various conditions.

CLAUDE S. BECK and F. R. MAUTZ, Lakeside Hospital, Cleveland:

Heart Injuries: Exhibit dealing with penetrating and non-penetrating types of heart injuries; illustrations of various acci-

dents producing cardiac injury; clinical classification—those with cardiac compression (surgical group), those without cardiac compression (nonsurgical group); pathology and clinical manifestations of each group; treatment of operative group, and nonoperative group; operative methods; illustrated by charcoal drawings and motion pictures.

CLAYTON J. LUNDY, Rush Medical College, Chicago:

Mechanism and Electrocardiographic Registration of the Heart in Health and Disease: Exhibit of charts and motion pictures showing the normal heart, six types of extrasystoles and of paroxysmal tachycardia, auricular flutter, auricular fibrillation heart block, acute coronary thrombosis and chronic arteriosclerotic heart disease. Heart action and electrocardiogram formation are depicted simultaneously.

GEORGE LEVENE, HENRY H. LERNER and EGON G. WISSING, Evans Memorial for Clinical Research and Preventive Medicine, Massachusetts Memorial Hospital, Boston:

The Roentgenoscopic Appearance of the Heart: Exhibit of a series of mechanical models in motion showing the appearance of the heart as seen under the fluoroscope, portraying rheumatic heart disease, syphilitic heart disease, arteriosclerotic heart disease and metabolic disturbances of the heart; each unit shows successive phases in the development and life cycle of a specific cardiopathy.

HARRISON S. MARTLAND, Office of the Chief Medical Examiner of Essex County, City Hospital, Newark, N. J.:

Pathology of Cardiovascular Disease: Exhibit of color transparencies showing typical examples of common and unusual cardiac lesions found at autopsy, together with a few enlargements and histologic appearances necessary to elucidate subject, arranged in order as a guide to the pathologic diagnosis of cardiovascular disease.

A. R. BARNES, Mayo Clinic, Rochester, Minn.:

Electrocardiographic Patterns of Diagnostic Importance in Certain Heart Diseases: Exhibit of photographs and electrocardiograms showing the electrocardiographic changes in acute anterior and acute posterior infarction; injection specimens of the normal coronary circulation and of a case of coronary occlusion; healing acute cardiac infarction; acute pericarditis complicating acute infarction; characteristics of the normal electrocardiogram; electrocardiograms in acute septic pericarditis; electrocardiogram in chronic left ventricular strain and of chronic right ventricular strain; in pulmonary embolism, and in chronic constrictive pericarditis.

HARRY GOLDBLATT, Cleveland:

Experimental Hypertension: Exhibit depicting (a) the work of other investigators designed to prove the renal origin of hypertension; (b) the method of renal ischemia for the production of hypertension by the author and collaborators, confirmed by others; (c) charts illustrating the work on dogs and monkeys designed to determine the mechanism whereby this type of hypertension is produced, and the value of various procedures designed to prevent or cure this type of hypertension; (d) photomicrographs and photographs of the organs and tissues of animals with experimental hypertension.

SAMUEL BELLET, Philadelphia:

Tuberculous Pericarditis: Exhibit of pathologic specimens of different types of tuberculous pericarditis, x-ray films showing the progress of this condition; photomicrographs, electrocardiograms and charts showing the incidence, racial susceptibility, age groups, the pathologic and clinical types and the important points in the diagnosis. Prognosis and treatment is also considered.

FRED L. ADAIR and EDITH L. POTTER, Chicago:

Congenital Heart Disease as Found in New-Born Infant: Exhibit of photographs and mounted specimens showing various anomalies of cardiac formation together with explanatory charts and diagrams; charts showing the external and internal appearance of the heart in the main groups of anomalies and diagrams showing the path of the blood stream in each condition; the relation of malformations to different periods of normal embryonic growth and a brief explanation of the development of the heart is included.

TIMOTHY LEARY, Boston:

The Evolution of Mitral Valvular Disease: Exhibit showing that the commonest pathologic lesion encountered in the human body is thickening of the contact edge of the mitral valve due to repair of lesions almost exclusively rheumatic in origin; the evidence suggests that infections of this type are almost universal and begin in childhood; in most human beings early infections are healed and remain so; in susceptible individuals, recurrent infections give rise to progressive deformity of the valve producing clinical mitral stenosis; enlarged photographs of mitral lesions, gross and microscopic, indicating the progressive character of the changes as acute rheumatic attacks succeed one another; motion picture illustrating the stages in progression from one phase to another.

HUGH ROBERTSON, Corinna Borden Keen Fellowship, Jefferson Medical College, Philadelphia:

Pulmonary Embolism: A Clinical Study of Its Cause and Prevention: Exhibit of models and drawings from actual dissections of the pulmonary artery, showing recent work on thrombus and embolism production; the types of patients who develop pulmonary embolism; an embolus lodging in the pulmonary artery; recent theories of prevention and treatment of pulmonary embolism.

M. C. WINTERITZ, Yale University School of Medicine, New Haven, Conn.:

Studies on the Pathology of Arteriosclerosis: Exhibit of drawings, films, photographs and specimens dealing with the anatomy and physiology of the blood vessel wall in health and disease, and presenting a new approach to the progressive changes grouped together under the term arteriosclerosis.

J. B. SCHWEDEL, New York:

Roentgen Cardiodynamics: Exhibit presenting a method and criteria of estimating cardiac enlargement, especially selective chamber enlargement, consisting of photographic prints of roentgenograms and specimens; explanatory charts, diagrams and postmortem specimens; the clinical significance of selective enlargement will be stressed.

HUGO ROESLER, Temple University School of Medicine, Philadelphia:

Correlation Between Anatomy, Pathology and Roentgenology of the Cardiovascular System: Exhibit of (a) normal and pathologic specimens cut in longitudinal sections, corresponding to the anterior and to both oblique views, permitting correlation between x-ray silhouettes as observed during life with the postmortem specimens, and giving instruction as to the inner topography of the silhouette; (b) x-ray films and gross postmortem specimens; (c) demonstration of the principle of the roentgenologic, volumetric reconstruction of the heart and great vessels, method of Palmieri, as illustrated by photographs and models.

A. J. NEDZEL, Chicago:

Experimental Endocarditis Due to Pressor Episode: Exhibit of photomicrographs, gross specimens and slides showing that pitressin injections cause endothelial changes on the heart valves, which cause the stickiness of the endothelium and the settling of floating bacteria; in due time a bacterial endocarditis develops; if no bacteria are present, the changes in the heart valves (mostly mitral) resemble a rheumatic (nonbacterial) endocarditis.

L. S. YLVIKAKER and HENRY B. KIRKLAND, Newark, N. J.:

Heart Size and Contour: Normal Variability Factors: Exhibit showing the variations in size, contour and position of normal hearts studied by means of roentgenograms, and the factors influencing these variations; deviations from normal have been thoroughly studied clinically to rule out disease; the importance of rigidly controlled and standardized technic is emphasized; the necessity of caution in diagnosing cardiac abnormalities on the basis of roentgenograms alone is stressed; x-ray observations are shown to serve rather than to direct further analysis of the heart condition.

A. CARLTON ERNSTENE, Cleveland Clinic, Cleveland:

The Heart in Hyperthyroidism: Exhibit of charts summarizing the effect of hyperthyroidism on the heart and circulation;

an analysis of the cardiovascular complications observed in 1,000 consecutive cases of hyperthyroidism, auricular fibrillation, auricular flutter, paroxysmal tachycardia, angina pectoris, cardiac asthma and congestive heart failure, and a synopsis of the management of cardiovascular complications in hyperthyroidism.

WILLIAM J. KERR, A. M. BASSETT, M. J. GOLDMAN and T. L. ALTHAUSEN, University of California Medical School, San Francisco:

The Synballophone, an Improved Stethoscope for the Lateralization and Comparison of Sounds: Exhibit demonstrating the construction and use of a new stethoscope which permits utilization of the function of the ear in locating the origin of sounds and in comparing their qualities; other acoustic devices of small size are used to illustrate the functions of the ear.

AMERICAN HEART ASSOCIATION, New York:

Educational and Exhibit Material of the American Heart Association: Exhibit of books, pamphlets and leaflets on various phases of cardiovascular disease.

EDUCATIONAL CLASSIFICATION

Government and National Organizations

The educational exhibits include those exhibits from national and state organizations and government institutions which are put on in the name of the institution rather than of individuals and which are intended to show progress in the particular activities with which those institutions deal.

These exhibits are not open to medal awards, but a special certificate of merit is presented to the best exhibit in this classification.

COMMITTEE ON EVALUATION OF SERODIAGNOSTIC TESTS, United States Public Health Service, Washington, D. C.:

The Performance of Serodiagnostic Tests for Syphilis in State Laboratories: Exhibit concerning an evaluation of the performance of serodiagnostic tests for syphilis in the state laboratories of this country. Thirty-nine state laboratories participated and performed a total of seventy-two tests, performance being evaluated on the basis of specificity and sensitivity; results obtained in state laboratories have been compared with results obtained by serologists who originally described many of the serodiagnostic tests; samples of blood from a large specimen were provided to all laboratories.

UNITED STATES PUBLIC HEALTH SERVICE, Division of Venereal Diseases, Washington, D. C.:

Modern Educational Measures for the Control of Syphilis: Exhibit of placards dealing with the public health and clinical aspects of the control of syphilis; data pertaining to the prevalence and control of syphilis; motion pictures dealing with the control of this disease.

AMERICAN SOCIAL HYGIENE ASSOCIATION, New York:

Gonorrhea: Its Present Status: Exhibit of (1) photographs, charts, lantern slides, other demonstration materials and reprints of authoritative medical and public health statements; epidemiologic studies; (2) summary of supplemental survey of research on the gonococcus and gonococcal infections; (3) the status of new therapeutic measures.

AMERICAN NEISSERIAN MEDICAL SOCIETY:

Gonorrhea: Its Present Status: Exhibit under the auspices of the American Neisserian Medical Society and in conjunction with the American Social Hygiene Association dealing with all important phases of gonorrhea.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES, Chicago:

Medical Education: Exhibit of charts depicting the various activities of the association, such as the study of student accomplishment in medical schools, correlated with their scholastic records in the arts colleges; study of applicants for admission to medical schools; the Intern Placement Bureau.

NATIONAL BOARD OF MEDICAL EXAMINERS, Philadelphia:

Exhibit of charts describing the work and progress of the National Board of Medical Examiners and the results of its examinations.

ADVISORY BOARD FOR MEDICAL SPECIALTIES:

Exhibit of charts, graphs and literature describing the work of the Advisory Board for Medical Specialties and of the examining boards for certification in medical specialties, including the American Boards of Ophthalmology, of Otolaryngology, of Obstetrics and Gynecology, of Dermatology and Syphilology, of Pediatrics, of Psychiatry and Neurology, of Radiology, of Orthopedic Surgery, of Urology, of Pathology, of Internal Medicine and of Surgery.

UNITED STATES PHARMACOPEIA:

An exhibit illustrating the series of articles recently published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION on "The Pharmacopeia and the Physician." These articles were prepared for physicians and to supply information concerning the use and prescribing of official medicines.

AMERICAN PHARMACEUTICAL ASSOCIATION, Washington, D. C.:

The National Formulary: Exhibit of some of the new and more important items of the National Formulary, Sixth Edition.

BUREAU OF CHEMISTRY AND SOILS, U. S. Department of Agriculture, Washington, D. C.:

(a) *Medicinal Products Made by Mold Fermentation*; (b) *Copper-Free Rosin for Plastic Work*; (c) *Hazards in Utilization of Agricultural Products*; (d) *Therapeutic Value of Phenothiazine*: Exhibit showing the methods and process of manufacture of medicinal products by mold fermentation; samples of copper-free rosin for plastic work and metal-free turpentine for medicinal use are shown and methods of manufacture are described; hazards arising from utilization of agricultural products, namely: dust explosions, spontaneous ignitions, explosives generated in extracting plants, suffocation from fermentation of gas; the therapeutic value of the insecticide phenothiazine.

CONNECTICUT STATE MEDICAL SOCIETY CANCER COMMITTEE, New Haven, Conn.:

Connecticut State Cancer Program: Exhibit of diagrams showing the organization of the Connecticut cancer program and demonstrating the coordination of the efforts of the state medical society and the state health department in fostering their movement; colored maps and graphs depicting variation in cancer mortality and age distribution of the population throughout the state; pin spot maps indicating existing clinic facilities for diagnosis and treatment in various Connecticut hospitals; standard tumor record forms used in institutions.

AMERICAN SOCIETY FOR THE CONTROL OF CANCER, New York:

Women's Field Army of the American Society for the Control of Cancer: Exhibit of charts and diagrams showing the objective and progress to date of the Women's Field Army of the American Society for the Control of Cancer since its inception in the early part of 1936.

NATIONAL CONGRESS OF PARENTS AND TEACHERS, Washington, D. C.:

Health Activities of the National Congress of Parents and Teachers: Exhibit featuring the activities of the National Congress of Parents and Teachers which relate to the development of health; (1) model portraying the Summer Round Up of the Children, an activity of the National Congress; (2) posters and booklets showing work of the Congress.

AMERICAN ASSOCIATION OF MEDICAL SOCIAL WORKERS, Chicago:

Exhibit of charts and reports of studies on social aspects of illness, rôle of the medical social worker and development of social service departments within hospitals.

AMERICAN OCCUPATIONAL THERAPY ASSOCIATION, New York:

Occupational Therapy: Exhibit of charts, photographs, case histories and other objects presenting the principles of occupational therapy and the results of such treatment.

AMERICAN PHYSIOTHERAPY ASSOCIATION AND VISITING NURSE ASSOCIATION OF CHICAGO:

Improved Physical Therapy Equipment for the Home Care of Anterior Poliomyelitis: Exhibit of photographs and models

of home-made apparatus for the care of patients, including such equipment as a tank for underwater exercises and apparatus for lifting the patient in and out of the water, improvised portable carts and other appliances; simple splints for maintaining correct posture and demonstration of the making of these splints; motion picture showing early physical therapy and orthopedic nursing care.

BUREAU OF ANIMAL INDUSTRY, U. S. Department of Agriculture, Washington, D. C.:

Diseases Common to Domestic Animals and Man: Exhibit of maps regarding bovine tuberculosis and Bang's disease in the United States; pathologic specimens and photographs.

ARMY MEDICAL MUSEUM, Office of Surgeon General, Washington, D. C.:

Registry Activities of the Army Medical Museum: Exhibit of photomicrographs, gross material and lantern slides showing type cases from the Registries of Ophthalmology, Otolaryngology, Lymphatic Tumors, Bladder Tumors and Dental Pathology.

FEDERATION OF AMERICAN SANATORIA:

A Few Things the Family Physician Should Know About Tuberculosis: Exhibit of charts and placards illustrating the pertinent message of what the family physician should know about tuberculosis.

NATIONAL TUBERCULOSIS ASSOCIATION, New York:

The Tuberculin Test: Exhibit of (a) photographs and text describing the technic of giving the tuberculin test; (b) moulages of tuberculin reaction; (c) text on the significance of the reaction; (d) photographs showing steps in the purification of tuberculin; (e) sample of purified protein derivative; (f) graphs on percentages of positive reactors.

CHILDREN'S BUREAU, U. S. Department of Labor, Washington, D. C.:

Maternal and Child-Welfare Services, 1937, Under the Social Security Act, Title V, Parts 1, 2 and 3: Exhibit showing (a) type of activity, (b) personnel paid in whole or in part from funds administered by the United States Children's Bureau, and (c) source of funds.

AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS, Registry of Technologists, Denver:

Exhibit of charts and placards illustrating the aims and work of the registry; the distribution of registered technologists; information on approved training schools; qualifications necessary for registration.

AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY, Committee on Deafness Prevention and Amelioration:

Exhibit of photographs, charts and lantern slides illustrating the activities of Committee on Deafness Prevention and Amelioration of the American Academy of Ophthalmology and Otolaryngology; methods of early detection of hearing deficiency in children; acoustically treated booth for insuring accuracy in making hearing tests.

THE UNITED STATES NAVY, Medical Department, Washington, D. C.:

Naval Medical Activity Pertaining to Preventive and Industrial Medicine and Public Health: Exhibit dealing with lung training (submarine escape device), life aboard ship, and messing system and its operation to prevent food poisoning; models of deep sea divers, diving pump and accessory gear; a series of submarine lungs in order of their development, some of which will be in cross section; photographs of the morbid anatomy of compressed air illness occurring in the U. S. Navy; recompression chambers for treatment of compressed air illness; data relating to the calculations of decompression tables estimating divers' air requirements and control of diving pumps; types of breathing apparatus; respirators and inhalators, and gas detecting instruments used in the U. S. Navy; a modified Haldane apparatus for determining cardiac output under varying atmospheric pressure—aviation and diving; shallow water diving outfit; sand blasting operations as employed in various U. S. navy yards; aviation oxygen breathing outfit

for high altitudes; full line of protective goggles, gloves, and respiratory equipment; model of a hospital ship and photographs of the later types of submarines.

AMERICAN MEDICAL ASSOCIATION

The exhibits from the headquarters group of the American Medical Association will be found in various parts of the hall. These exhibits are not open to awards.

COUNCIL ON PHYSICAL THERAPY:

Exhibit of apparatus demonstrating by vision, sound and touch how diathermy and short wave diathermy will heat the body tissues without causing electrical muscle stimulation (shock); charts and histologic specimens of damaged monkey tissues caused by severed nerves demonstrating effects of electrical muscle and nerve stimulation versus massage and active motion; charts bearing on the Council's educational program.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS:

Exhibit of statistics on (1) medical education; (2) medical licensure; (3) hospitals; results of the survey of medical education; methods of evaluating the work of medical schools; publications of the Council, including essentials and revised lists of hospitals approved for residencies in specialties, hospitals approved for training interns, schools for laboratory technicians, schools for physical therapists and schools for occupational therapists.

BUREAU OF HEALTH AND PUBLIC INSTRUCTION:

Doctors Must Be Health Teachers: Exhibit showing four principal mediums of publicity which local medical societies can use for furthering health education in their communities: newspapers, radio, meetings and pamphlets; what the local societies can do along these lines, and how the Bureau of Health and Public Instruction is prepared to help them.

COUNCIL ON PHARMACY AND CHEMISTRY:

Exhibit dealing with an exposition of Council studies and activities, special reference being made to vitamins and hormones.

BUREAU OF LEGAL MEDICINE AND LEGISLATION:

Exhibit of posters and charts showing (1) activities of the bureau and (2) the prevalence or effect of certain laws of interest to the medical profession, such as the Federal Social Security Act, and laws and bills relating to the basic sciences, narcotic drugs, hospital insurance, health insurance, medical liens, reporting of gunshot wounds, annual registration of physicians, cults, and the corporate practice of medicine.

AWARDS

There will be two classes of awards consisting each of (a) gold medal, (b) silver medal, (c) bronze medal and (d) three certificates of merit.

[NOTE.—The special (subsidized) exhibits (anesthesia and fractures) and the exhibits of the headquarters of the American Medical Association are not open to awards.]

CLASS I

Awards in class I are made for exhibits of individual investigations, which are judged on basis of originality and excellence of presentation.

CLASS II

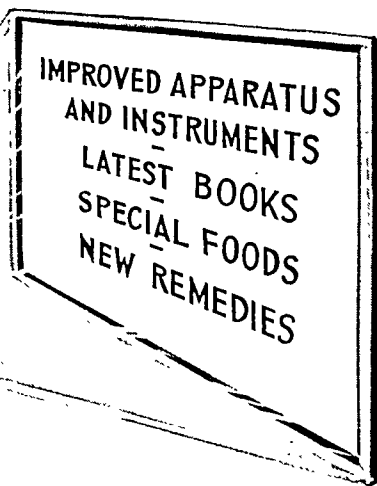

Awards in class II are made for exhibits that do not exemplify purely experimental studies, which are judged on basis of the excellence of correlating facts and excellence of presentation.

Medals are awarded only to individuals. A special certificate of merit will be awarded to the best educational exhibit in the Educational Classification (this includes exhibits by national societies).

The Committee on Awards will be composed of five persons. It will make the decisions on Wednesday.

The names of the members of the Committee on Awards will not be available until after the decisions have been published.

The TECHNICAL Exposition...

A SHOWING BY MORE
THAN 220 FIRMS

* Apparatus and Instruments

Extensive Aloe Display

The new De Bakey Blood Transfusion Instrument and also a complete general line of surgical instruments and sundries will be shown by A. S. Aloe Company in Booth 159. In Booth 171 the new Aloe Steeline physicians' furniture, in a full selection of colors, will be displayed, together with the new Aloe Short Wave and other physical therapy equipment. In Booth 105 the firm will show a complete line of clinical laboratory equipment. Competent representatives will be in attendance.

New Surgical Handles and Blades

Stop at Booth 177, where the American Safety Razor Corporation will exhibit its latest surgical handles and blades. The attendant in charge will be glad to supply you with samples of the new laboratory-developed blades, which are now standard equipment in many of the leading hospitals throughout the country.

For Surgeon and Urologist

Advances in urological armamentarium during the past year will be shown in Booth 83, by C. B. Bard, Inc. In addition to their complete line of Eynard (France) products, the firm will show an absolutely odorless colostomy pouch, electrically lighted ureteral catheters, Latex soft rubber catheters and drains. As usual, guests will not be solicited to purchase.

Will Show Rib-Back Blade

The Bard-Parker Company, Booth 103, will demonstrate the outstanding features of their Rib-Back blade, which incorporates new standards of cutting efficiency and economy. Also *the Sharp* they will show a complete line of stainless steel scissors with renewable edges, and a selection of quality forceps with the Lahey lock.

(Continued on page 1618)

PHYSICALLY, the Technical Exposition is impressive because of its sheer size. This year, in the Auditorium at Atlantic City, the Exposition will completely cover an area of more than an acre and a half. The products of more than 200 manufacturers will be shown. The articles on display will cover practically the whole scope of the physician's needs, ranging from a tiny speck of radium to heavy X-Ray or Ultra-Violet generators of huge proportions.

BUT, the Technical Exposition is more than a mere assembling of products into one place—behind it is a well defined educational purpose. True, manufacturers are present to sell their products, but they realize that the best way to sell a product is to show how it will serve the physician's needs. Consequently, in most of the exhibits the visitor will find not merely products, but capable, trained, experienced representatives who know the practical applications of those products.

FURTHERMORE, many manufacturers make it a point to introduce their new items at the Exposition. Often the visitor will find present the scientist or technician responsible for the development of the product. Physicians are, therefore, urged to take ample time to visit the exhibits. Each and every display has some definite point of contact with the medical practitioner, be it pharmaceuticals and biologicals, medical books, instruments, apparatus, electrical equipment, dietetic products, or specialized services.

THE entire Technical Exposition will be located on the main floor of the Auditorium. It will be open from 8:30 A. M. until 6:00 P. M. daily, closing at 4:00 P. M. on Friday. Practically all of the activities of the Convention, including general meetings, section meetings, etc., will be housed in the Auditorium, and visiting physicians will, therefore, find it convenient as well as pleasant and profitable to make leisurely, unhurried visits to the various exhibits.

WILL C. BRAUN, Superintendent of Exhibits

Demonstrating an actual manufacturing process.

Made for the Profession

Becton, Dickinson & Company will be represented with an extensive display of products, including fever thermometers, syringes, needles, Ace bandages, Asepto syringes, diagnostic instruments and professional leather goods. Of unusual interest should be the demonstration of blowing and processing syringes from the glass tube, and the actual making of B-D fever thermometers. Booths 134, 135, 136 and 147.

New All Steel Office Outfit

The Frank S. Betz Company will have on display in Booths 198 and 199 a complete line of up-to-date surgical instruments, physicians' bags, medicine cases, an all steel office outfit finished in hand grained walnut, and other new merchandise. Do not fail to call at the booth for your souvenir.

Modern Surgical Lighting

All surgeons are invited to call at the Wilmot Castle Booth, No. 220, and inspect the satisfying features of the Castle Light for operative work in either hospital or office. Also there will be on display the new models of the Castle Sterilizer, with its safety, automatic security and pleasingly modern style.

Cayo Power Instruments

In Booth 256-H, the Cayo Company will demonstrate their bone instruments and explain the technic they use in various operations. Among the features worthy of note will be the Cayo method of entering the surgical field without danger of contamination.

A New Scalpel Blade

The Crescent Surgical Sales Company will show their new scalpel blade, which has the scientifically developed angle of 16 degrees and is one-third thicker throughout the entire body of the blade. This greater thickness of metal gives more rigidity and a definitely sharper edge. Free samples are available to surgeons. Booth 210.

Sutures for Every Purpose

Their complete line of sterile sutures will be displayed by Davis & Geck, Inc., in Booth 216. This line includes a wide variety of interesting products especially designed for various situations in accident

and emergency work, as well as in general surgery and the specialties. A further feature of the exhibit will be motion pictures in full color, showing various operative procedures.

Fracture Appliances

In Booth 117 the DePuy Manufacturing Company will show late developments in high-grade splints, made of the finest quality of materials. The firm invites physicians to call and give their criticisms and suggestions. Trained men will be in attendance.

DeVilbiss Display

The complete DeVilbiss line of atomizers, steam vaporizers and nebulizers will be on display in Booth 203. Specially featured will be illustrations, based on X-ray research, graphically showing the coverage afforded by the atomizer in the application of solutions to the nose and throat. Copies of these illustrations for reference may be secured from the representative in charge.

Resuscitation Apparatus

Resuscitation equipment on the principles of Yandell Henderson, Flagg and McCormack, as sponsored by the Society for Prevention of Asphyxial Death, will be shown in Booth 51 by the Foregger Company, which makes a specialty of gas therapy. This firm will also have on display interesting new developments in carbon dioxide absorption apparatus for inhalation anesthesia.

Electric Rotary Pump

In addition to exhibiting their complete line of surgical specialties, including the circumcision clamp, the umbilical clamp, etc., the Gomco Corporation will exhibit their new electric rotary pump, with motor and compressor built into one compact unit.

Gas Anesthesia Equipment

The Heidbrink Company, Booth 232, will have an extensive display of the latest developments in gas anesthesia and oxygen therapy equipment. The exhibit will be in charge of a competent representative, who will be glad to discuss or demonstrate any piece of equipment shown.

Suction and Pressure Apparatus

The Penn Surgical Manufacturing Company will exhibit in Booth 207 the latest development in suction and pressure apparatus, a noiseless suspended power motor driven rotary compressor pump, the complete apparatus mounted on coil springs which eliminates all noise and vibration.

Surgical Instruments

In Pfau's American Instrument Company Booth, 132, specimens showing the various stages of Dr. Lempert's appendectomy operation will be shown. There will also be diverse anatomical models of new plastic, and ear, sinus and laryngo-bronchoscopic instruments on display.

New Treatment Units

The Philadelphia Surgical Instrument Company plan to display, in Booth 256-C, the new Collens-Wilensky apparatus for intermittent venous occlusion in treatment of thrombo-angitis obliterans and other diseases of the blood vessels. The firm will also show the new Wappler cold cautery scalpel, as well as their popular low-priced treatment cabinet, which embodies in one unit suction and pressure pump, cautery and diagnostic light equipment.

Chevalier Jackson Instruments

An opportunity to examine a modern, complete showing of thoracic instruments, many new brain and eye, ear, nose and

throat instruments, and the well known Chevalier Jackson bronchoscopic instruments will be afforded by the George I. Pilling exhibit. Their pneumothorax apparatus will include a wide choice of both hospital and portable types. Booths 187, 188

Portable Operating Lights

The Prometheus Electric Corporation Booth 120, will demonstrate an unusual complete line of lamps for specialized surgical illumination. Portable operating lights for all purposes will be featured from the smaller minor surgery model to the larger major auxiliary type. Particular emphasis will be placed upon the problem of emergency illumination when current fails. Modern sterilizing equipment and other items will also be shown.

Suction and Pressure Apparatus

A visit to the J. Sklar Manufacturing Company Booth, 258, will give opportunity to examine a complete line of improved designs in suction and pressure apparatus, including the new, modern Moorhead Cabinet. There will also be a showing of Sklar's American-made stainless steel surgical instruments. Of particular interest will be the Dr. A. T. Moore instruments used in treatment of fracture of the hip joint.

Hearing Aids and Audiometers

The Sonotone Corporation will exhibit new developments in electrical hearing aids, including the Sonotone Audicle, which provides selective amplification in different frequency ranges and which is fitted to individual needs by means of a new instrument, the Audioscope. Also on display will be the Sonotone Audiometer, a high precision instrument for measuring hearing loss, providing seven fixed frequencies sweep frequencies and special bone and air conduction receivers. Booth 68.

Fracture Equipment

A number of new items recently added to the line of Zimmer Manufacturing Company will be displayed in Booth 178. All doctors interested in skeletal traction are urged to investigate the advantages of the Clayton attachments for the leg and arm reduction apparatus. Representatives in charge of the booth will explain the Smith-Peterson technic for nailing fractures in the neck of the femur, and instruments for this work will be shown. A complete line of splints will also be on display.

Peripheral Vascular Equipment

The U.M.A. Inc. plan to exhibit (Booth 110) the intermittent venous occlusion apparatus described in The Journal A.M.A. of Dec. 12, 1936, by Doctors Collens and Wilensky. This apparatus is concerned with increasing the collateral flow to extremities suffering from organic obliterative arterial disease, and is used in the treatment of thrombo-angitis obliterans and other peripheral vascular affections. The firm will also exhibit a new mercury skin thermometer, a new thermocouple and an oscilloscope.

For the Operating Room

The Mont R. Reid major operating table, which comprises many mechanical ingenuities, will be shown by Max Woehner & Son Company in Booth 111. Also a new design of operating room illuminating fixture, comprising three circuits, including an emergency circuit, will be displayed, as well as alternate vacuum-pressure outfits for treatment of sinus trouble and congestions, and an attractive display of modern, high class instruments.

Fracture Splints

The complete line of Roger Anderson fracture splints will be shown in Booth 15 by The Tower Company, Inc. Of special interest will be the constant contact method

of treating fractures of the hip with the Well-Hip splint. Actual demonstrations on aluminum models and new motion pictures on technique will be featured. The ambulatory method of treating fractures will also be exhibited.

* Dietetic Products

American Can Exhibit

All registrants are cordially invited to call at the American Can Company Booth, where information will be available concerning those aspects of commercially canned foods which are of greatest interest to the medical profession. Literature on canned foods designed specifically for the physician's use will also be on display. Booth 45.

Borden's Eightieth Year

A warm welcome awaits physicians at the Borden Booth, 128. Specially trained representatives will gladly provide information on Borden products, notably Dryco, Special Dryco, Klim, Beta Lactose, Merrell-Soule prescription products and Borden's irradiated evaporated milks.

Irradiation of Milk

The Carnation Company invites you to visit Booth 248, where you will see the seven important steps in the production of Irradiated Carnation Milk presented by means of animated illumination. The methods and equipment used in testing and protecting the quality of Carnation Milk will also be demonstrated.

Clapp's Strained Baby Foods

Harold H. Clapp, Inc., will have on display in Booth 228 their complete line of 16 varieties. Representatives will be glad to discuss the individual characteristics which feature Clapp's Baby Foods and make them outstanding in their field. Literature and samples will be available to physicians.

Foods for the Diabetic

Sugar-free chewing gum, sugar-free desserts and sugar-free sweets will be shown by Chicago Dietetic Supply House, Inc. Also included will be a complete line of low carbohydrate foods for sugar and starch restricted diets, including flours, cereals, canned fruits and vegetables. Special features will be Cellu "Juice-Pak" fruits, packed in natural juice without added water or sugar, and Cellu Fruit Juices, natural, undiluted juices packed for special diet purposes. Booth 138.

Karo-Dextrose Exhibit

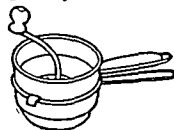

In Booth 253, Corn Products Refining Company will present interesting data and literature on the uses and administration of Karo Syrups and pure Dextrose. Representatives will show why Karo Syrup is of special interest to pediatricians, and will supply complete information, culled from world literature, explaining to physicians generally the successful uses for Dextrose in many types of disturbances.

New Products for Infants

Two new foods for the infant, Strained Apricot-Apple Sauce and Strained Liver Soup with Vegetables will be shown by Gerber Products Company in Booth 247. Their two types of literature, for distribution to patients and for professional use, respectively, will be on display, and will be mailed, together with samples of the foods, to registrants at the booth.

Easy Way to Strain Foods

In Booth 73 the Foley Manufacturing Company will demonstrate how easily and quickly fresh cooked vegetables and fruits are mashed or strained with the Foley Food Mill, made of steel, rust-proof, acid-proof, and easy to clean. It will be shown in three sizes.

Four Exhibits by Mead Johnson

Mead Johnson and Company will maintain four points of interest for the physician, as follows: A general exhibit, with all products and services on display, and a showing of original Posthast paintings; medical motion pictures, with a number of new subjects of special interest to pediatricians; Pabulum exhibit, featuring charts and showing appetizing dishes which can be made with Pabulum; Oleum Percomorphum exhibit, with color transparencies and aquarium containing live members of the order Percomorphi. Booths 1, 2, 127, 263, 264 and Room A.

General Mills Display

In addition to showing Embo (Wheat Embryo), "Kitchen-Tested" Flour, Wheaties, Bisquick, and Soft-silk Cake Flour, with literature on their nutritive value, General Mills, Inc., will feature an unusual development for inspection of physicians, at Booth 269.

Dole Pineapple Exhibit

Glamorous island scenes, true to Hawaii in brilliant color and subject, will distinguish the Hawaiian Pineapple Company Booth, 271. In this hospitable atmosphere the company will serve Dole Pineapple Juice, the natural unsweetened juice of sun-ripened fruit. The complete line of Dole Pineapple products will also be displayed and sampled. Specially featured will be the new "Royal Spears" and "Dole Pineapple Gems."

Rennet-Custard Desserts

In Booth 88 The "Junket" Folks, Chr. Hansen's Laboratory, Inc., will demonstrate how quickly and easily rennet-custards are prepared with "Junket" Rennet Powder and Rennet Tablets. Prepared from fresh milk, rennet-custards are recommended

attendant will be on duty.

Try a Glass of Tomato Juice

H. J. Heinz Company, makers of the 57 Varieties, invites you to visit their new exhibit featuring strained foods, breakfast

cereals, tomato juice and olive oil. A cold drink of Heinz Tomato Juice will be served to visitors, and physicians are invited to register for the fourth edition of the Nutritional Chart, which has been revised to keep abreast with the rapid advances in the field of nutrition. Booth 204.

Evaporated Milk Irradiation

A miniature irradiator, actual rays for the enrichment of the milk with vitamin D, will be displayed by the Irradiated Evaporated Milk Institute, Booth 125. Literature will be available on infant feeding.

Sanka Coffee to Be Served

Visitors are invited to stop at General Foods Booths 223 and 224 to have a cup of Sanka Coffee, from which 97% of the caffeine has been removed without affecting the rich flavor and aroma of the coffee. The new D-Zerta, an attractive sugar-free gelatin dessert for the diabetic or others on a low-carbohydrate diet, will also be on display.

Mellin's Food Display

Physicians are invited to call at Booth 166 to discuss their feeding problems with representatives of Mellin's Food Company. The latter will be glad to furnish information concerning the favorable effect of Mellin's food on the digestibility of milk, and other factors which commend it as a milk modifier for infant feeding and for special diets of adults.

Have a Cup of Coffee

For the thirteenth consecutive year the Kellogg Company will have a booth in the Technical Exhibit. Kaffee Hag Coffee, from which 97% of the caffeine has been removed, will be served in Booth 270. You are invited, when tired of walking the boardwalk and attending meetings, to stop and have a refreshing drink of this beverage. A well informed representative will be in charge.

One of many busy corners at last year's Exposition.

Sampling one of the many beverages.

A Completely Modified Milk

Similac, a completely modified milk for infants deprived of breast feeding, will be displayed by M & R Dietetic Laboratories, Inc., Booth 186. Qualified representatives will gladly explain the value of the zero curd tension of Similac as it applies to both normal and special feeding cases.

See the Mechanical Cow

Visitors to Booth 58 will be entertained by the famous Nestle's Milk Products, Inc., Mechanical Cow, a versatile creature who blinks her eyelids, wags her head, flicks her tail, and punctuates these actions with contented moos. Literature and samples of Lactogen, Hylac and Nestle's Food will be available to physicians.

S. M. A. and Smaco Products

S. M. A. Corporation, Booths 122 and 123, will display S. M. A., the antirachitic and antispasmodic breast milk adaptation; Protein S.M.A. (Acidulated) for premature and other infants requiring high protein intake; Smaco Carotene, in crystal, liquid and capsule forms, plain and combined with Vitamin D concentrate; Hypo-Allergic Milk, liquid and powder; Alerdex, protein-free maltose and dextrins; and other products.

Evaporated Milk Plant

An actual working model of a milk condensing plant in miniature, every part constructed to scale, will be exhibited by Pet Milk Company in Booth 107. It will show the method by which the milk is processed from the time it is received from the farmer until it is sterilized in the can ready for use. A dozen miniature Pet Milk cans, one of which will charm any child patient, will be given to each physician who visits the Pet Milk Booth.

Tomato Juice on Tap

Kemp's Sun-Ray Pure Tomato Juice will be dispensed free to thirsty doctors at the convention. The Sun-Ray Company will display a trophy won for the high quality Indiana tomatoes used, and will call attention to the patented process by which the juice is made to insure vitamin potency, non-separation, and smooth, full-bodied flavor.

Palatable Products for Baby

Strained Foods for babies will be exhibited by Stokely Brothers & Company in Booth 85. Four new varieties, Liver Soup, Beef Broth, Unstrained Soup and Apple Sauce will be shown in addition to the usual line—all packed in golden enamel lined cans, correctly seasoned with salt or sugar under laboratory control, and all distinctly palatable. Visitors are invited to call.

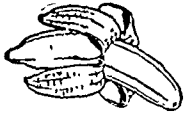

To Serve Vitamin D Milk

At Booth 259, Vitex Laboratories, Inc., will again serve visiting physicians and their friends with refreshing Vitex Vitamin D Milk, each quart of which will contain 400 U.S.P. units of vitamin D, extracted from cod liver oil by the Vitex process. This is the same milk which is sold to thousands of families in over 250 major cities of this country.

Will Serve Banana Milk Shake

Visitors are cordially invited to call at the United Fruit Company's Booth, 192, and sample a delicious ripe banana drink made from the fresh, fully ripe fruit and mixed with milk. The latest information, developed by research, will be available on the food value and uses of the banana.

Wisconsin Foundation Exhibit

The extensive educational work of the Wisconsin Alumni Research Foundation will be the basis of their exhibit in Booth 257. The Steenbock irradiation process and control of irradiated Vitamin D products to insure uniform Vitamin D potency will be demonstrated and described. The display will also include other recent scientific findings.

* Diagnostic Apparatus

See the A. B. C. Hemometre

In Booth 29 the American Medical Specialties Company, Inc., will present the A. B. C. Hemometre, a new instrument for taking the hemoglobin content of the blood. By employing an entirely new principle, a hemoglobin count can be taken with the instrument in a few minutes' time, without fuss or bother. The Hemometre is extremely simple to operate and remarkably accurate in results. All physicians are invited to call.

For Cardiac Diagnosis

Notable among the "Hindle" Electrocardiographs and other apparatus to be exhibited by Cambridge Instrument Company in Booth 126, will be the Electrocardiograph-Stethograph, which makes it possible to record the electrocardiogram and heart sounds simultaneously in the same record. The Cambridge Stethograph, a small portable instrument which amplifies heart sounds as an aid in auscultation and records them as well, will also be shown.

The Bio-Photometer

The Bio-photometer, a new clinical diagnostic instrument which makes it possible to detect even mild degrees of Vitamin A deficiency, will be shown at Booth 112 by Frober-Faybor Company. Representatives will demonstrate how easy it now is to test children and adults for Vitamin A deficiency and to measure response to Vitamin A therapy.

Will Show Stomach Camera

Gastro-Photol Laboratories will exhibit in Booth 230 the latest model of a camera for direct photography of the interior of the stomach. Actual photographs of the interior of the stomach, normal and pathological, will be on display. A motion picture illustrating the use of this ingenious instrument will also be shown.

Blood Chemistry Units

LaMotte blood chemistry units for the physician will be shown in Booth 210. The exhibit will be in charge of chemists who will be glad to go over any of the tests with physicians who might be interested. The Improved Kline Slide Test for syphilis will also be shown, along with other standard LaMotte diagnostic units for use in blood and urine tests.

Microscopes and Accessories

Various types of research and laboratory microscopes and accessories will be shown in Booth 89 by E. Leitz, Inc. Also on display will be the recently developed Universal Microscope and Photo-Micrographic Apparatus Panphot; the Tyndallometer, a new dust measuring device; and the well known Leica Camera, with a complete line of accessories especially adaptable for clinical photography and photography of gross pathological specimens.

Diagnostic Equipment

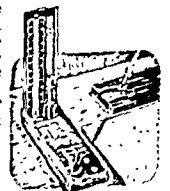

The latest Sanborn Company metabolism and electrocardiograph equipment will be shown in Booth 146. Interesting demonstrations will be made of the Sanborn Metabolism Tester, Model E-I-S, which now features a simple slide rule for rapid computation of the basal metabolic rate. Also the new Sanborn Cardiette, portable electrocardiograph, 1937 model, and the Sanborn Standard Electric-Portocardiograph, for hospital heart tests and cardiac research, will be exhibited.

Optical Instruments

The Spencer Lens Company will have an interesting display of binocular and monocular microscopes; paraffin and freezing microtomes; delineoscopes; bright line counting chambers; as well as popular accessories. This exhibit, Booth 10, will afford a splendid opportunity to examine the new dark field setup, both as to equipment and technic.

A New Tycos Instrument

You can inspect the new Tycos Mercuial Blood Pressure Instrument, along with the latest models in portable and desk style aneroid instruments of the Taylor Instrument Companies, in Booth 212. Their representatives will be glad to explain the liberal Tycos exchange plan.

To Show New Laryngoscope

At the Welch Allyn Booth, No. 28, will be exhibited a new Laryngoscope of the type used in securing films of the vocal cords shown at the annual meeting; also important developments in Otoscope lamps;

* Medical Books

"Practitioners Library" on Display

Their entire standard line of medical works will be displayed by D. Appleton-Century Company in Booth 225. The "Practitioners Library of Medicine and Surgery," edited by Dr. George Blumer, will be on display, including the new twelfth volume, "Hygiene and Preventive Medicine." The third volume of the new "Postgraduate Surgery," "Legal Medicine and Toxicology," "Textbook of Diagnostic Roentgenology," "Diseases of the Nose and Throat," and other works will also be shown.

New Blakiston Books

In Booth 158 P. Blakiston's Son & Company will exhibit the following new volumes: Balme's "Relief of Pain"; Knudsen's "Oral Diagnosis"; "Punch and Scases"; Sheldon's "and Childhood"; Underhill's "Toxi-"; "Historical Notes in the 'Recent Ad-"; "Surgery," Bray's "Allergy," and Cameron's "Endocrinology."

F. A. Davis Exhibit

You will find at the F. A. Davis Company Booth, 170, many outstanding new books, including Troncoso's "Internal Diseases of the Eye and Atlas of Ophthalmoscopy"; Loewenberg's work on "Clinical Endocrin-"; "Urinalysis and Injection Treat-

ment," and the Piersol "Cyclopedia of Medicine."

Lea & Febiger Books

The following new works will be exhibited by Lea & Febiger in Booth 153: Atkinson's "The Ocular Fundus"; Brahdry & Kahn's "Trauma and Disease"; Davidoff & Dyke's "Normal Encephalogram"; Davis' "Neurological Surgery"; Levinson & MacFate's "Clinical Laboratory Diagnosis"; Matthe's "Chemical Procedures"; Rowe's "Clinical Allergy"; Saxl's "Pediatric Diets"; and many other noteworthy medical books.

New Thyroid Work

New books to be displayed by the J. B. Lippincott Company, Booths 151 and 152, will include Emerson's "A Textbook of Medicine"; Pfaunder and Schlossmann's "Diseases of Children"; McBride's "Disability Evaluation"; Herrmann's "Passive Vascular Exercises"; Peham and Amreich's "Operative Gynecology"; and Kirschner's "Operative Surgery." Also a new work, on "The Thyroid and Its Diseases," by Means, and "An Atlas of Hematology," by Dr. Roy R. Kracke, will be exhibited.

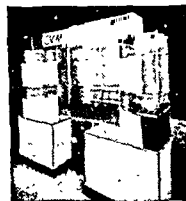

Macmillan Medical Works

Among the recently published Macmillan books to be exhibited are the new second edition of White's "Heart Disease," Levy's "Diseases of the Coronary Arteries and Cardiac Pain," Guedel's "Inhalation Anesthesia," Diethelm's "Treatment in Psychiatry," the new edition of Barclay's "The

To Show Newer Publications

New publications of the Mosby Company which include

Mansfield's "Materia Medica, Toxicology and Pharmacognosy"; Hollender's "Physical Therapeutic Methods in Otolaryngology"; and Hirschman's "Synopsis of Ano-Rectal Diseases."

Loose-Leaf Medical Books

Thomas Nelson & Sons invite you to visit their exhibit in Booth 66. The Nelson "Loose-Leaf Medicine," "Loose-Leaf Surgery," the new publication, "Loose-Leaf Diagnostic Roentgenology" (many volumes in one), and the new semi-annual replacement pages, showing the latest advances in medicine and surgery, will be on display.

From the Oxford Press

Of particular interest in the Oxford University Press display of medical books, Booth 176, will be the Oxford "Loose-Leaf Medicine." Representatives will be on hand to show this collection of monographs by leading authorities and the method employed to keep it constantly up to date. Another standard work to be shown is the new sixth edition of "Applied Physiology," by Samson Wright.

New Pages for Old

In Booth 233 the full line of loose-leaf medical works published by W. F. Prior Company will be exhibited. Included will be Tice's "Practice of Medicine," Lewis' "Practice of Surgery," Mock, Pemberton and Coulter's "Principles and Practice of Physical Therapy," Davis' "Gynecology and Obstetrics," and the new "Practice of Pediatrics," by Brennemann.

Saunders Medical Publications

Important new books and new editions to be shown by W. B. Saunders Company, Booth 154, will be the rewritten Warbasse-Smyth's "Surgical Treatment"; the new (1937) "Mayo Clinic Volume"; Jackson's "The Lar"; "Preopera"; Gr; Tuft's "Cal Diag"; and Arte "Textbook"; and other

"Talking Book" on Exhibit

A "talking book" will constitute the exhibit of "Surgery, Gynecology and Obstetrics," official journal of the American

Outstanding New Books

In Booth 245 the exhibit of the William Wood & Company Division of the Williams & Wilkins Company will provide an excellent opportunity for personal examination of several outstanding new books of the year, including Kurzkrok's "Endocrines"; Best & Medical; al Neu-; itamin-; Diagno-; works.

A. M. A. Publications

Periodicals, pamphlets and reprints from the A. M. A. Press, as well as the American Medical Directory, Index Medicus and other books, will be found in Booth 265. Adjacent, in Booth 266, will be a colorful presentation of Hygeia, The Health Magazine. Representatives will welcome visitors and discuss the value of Hygeia to the physician.

* Miscellaneous

Aznoc's Employment Service

An experienced representative of Aznoc's National Physicians' Exchange will be on hand in Booth 172 to offer the services of this organization to medical men and hospital executives who are considering additions or changes in office or hospital personnel. Available applicants include physicians, nurses, dietitians, technicians, or other medical assistants. This service is free to employers. Persons seeking an appointment or contemplating a change in employment are also invited to call.

See the New Buicks

Buick—exhibiting for the first time at any A. M. A. Convention—will offer for inspection and approval of visiting physicians two beautiful Buick models. Those physicians who have not seen the latest Buick developments have a delightful treat in store. The Buick display and demonstration will be in the Corridor Lobby. There will be on hand a corps of ex-

The new and standard books for first hand examination.

Checking over a new edition.

perienced demonstrators who will be glad to answer any questions concerning these stunning, new, beautiful Buicks.

New Elastic Stocking

Visitors to Booth 268, the Bauer & Black exhibit, will be interested in a demonstration of a new elastic stocking. The two-way stretch feature of the garment will be shown with a special machine which will stretch and re-stretch continuously for the duration. In addition to this will be an interesting plate line of surgical supplies.

Motion Picture Equipment

From Booth 27, Bell & Howell will provide official 16 mm. projection service and equipment supply for the Convention. Both sound and silent Filmo Projectors will be available at reasonable rental rates. The exhibit will feature the new Filmo 8 mm. Camera, and in contrast, the new semi-professional Filmo 70-F Camera with motor or hand-crank drive and 400' film magazine.

Clay-Adams Exhibit

Anatomical charts, models, skeletons, skulls and obstetrical phantoms and dolls will be shown by Clay-Adams Company in Booth 88. The exhibit will also include hemoglobin test apparatus, "Kosmoplast" ready-to-put-on dressing, "Gold Seal" hypodermic needles, small electric sterilizers and centrifuges, new duodenal tube and other specialties for doctor, surgeon and laboratory technician.

Skin Graft Dressing

The Perforated Form of the "Cilkloid" Surgical Dressing Tissue will be featured in Booth 3. Its use over a period of years has demonstrated its usefulness as a non-adherent dressing for skin grafts, and visiting doctors can examine it for this and other purposes. The Impervious Form of the Dressing will also be exhibited.

Kodachrome Color Film

Color photography of medical subjects as stills and 16 mm. motion pictures will be exhibited in all their vivid brilliance at Booths 79 and 80 of the Eastman Kodak Company. The method of exposing Kodachrome, the new color film, will be explained by experts. The newest line of Kodaks, Cine-Kodaks, and the Kodaslide projector will be on display, in addition to numerous photographic and radiographic examples of medical subjects.

G. E. Lamp Display

At Booths 60 and 61, the Incandescent Lamp Department of the General Electric Company will have meters continuously indicating the intensity of ultraviolet and light outdoors. By means of a miniature school room, the effect of variations of daylight upon the illumination in the class room will be demonstrated. Three-lit and I. E. S. Study Lamps, as well as ultraviolet and infrared equipment for use in the home and office, will be on display.

Normal Menstruation Study

An unusually complete study of normal menstruation will be exhibited in Booth 53 by International Cellucotton Products Company. The exhibit will feature a graphic presentation, in color, of the normal cycle of menstruation with its related endocrine factors. There will also be charts and graphs showing results of a six years study of 400 cases of normal menstrual loss between the ages of 12 and 48.

"One Writing" Record System

The McCaskey Register Company, in Booth 20, will call attention to their "One Writing" system, which offers the physician a convenience and saving due to the remarkable visibility and accessibility of individual record information. Every physician will be given an opportunity to see what four never failing assistants, working as one, will mean to him in profitable practice management.

Medical Opportunities

To those who seek medical personnel or new opportunities in the medical field, the Medical Bureau will offer the facilities of their organization in Booth 161. Here you may leave your request for any medical employee you may need—physician, dentist, hospital executive, graduate nurse, dietitian or technician—without charge for the service to employer.

Medical Case Histories

If you find record keeping an onerous task; if you are interested in a system that shows at a glance the case you want, how many calls you made and when, the patient's history, the developments, diagnosis and treatments, as well as the financial status of each case, spend some time in Booth 118 for the purpose of investigating the Medical Case History Bureau. All of the history forms are shown there as they are actually kept in their cabinets.

* Pharmaceuticals and Biologicals

"Council Accepted" Specialties

Abbott Laboratories will present a beautiful new assortment of a selected assortment of D. R. L. arsenicals, oils, pollen extracts, barbiturates, assorted ampoules, ephedrine and others are featured at the exhibit. A hearty welcome awaits you, and discussion of your clinical experiences with Abbott products will be most welcome.

Specialties by Calco

glu am
Calco
goumoux, and Crystal Violet Jelly-Calco, will be displayed in Booth 218, by the Calco Chemical Company, Inc. Their representatives will be pleased to direct the use of Urganin in the various cardiac conditions, and to explain the applications of all the other Calco

Professional Protection

The Medical Protective Company, which has concentrated upon legal liability problems of the medical profession for the past 38 years, will be represented at Booth 196. A representative will be glad to present their protection plan, to explain the peculiar relation of the doctor to the law which governs your practice, or to discuss any particular phase of professional liability in which you are especially interested.

Philip Morris Cigarettes

Philip Morris & Company, Ltd., Inc., will demonstrate the method by which Philip Morris cigarettes are made and in which diethylene glycol is used as the hygroscopic agent. According to tests, this method produces a cigarette which is mild and delightful and appreciated by smokers with sensitive throats. Booth 101.

New York Medical Exchange

You are invited to visit Booth 31, where the New York Medical Exchange offers its highly specialized placement service to the medical and allied professions, without cost to employer. Problems of reorganization, staff additions, appointments and changes of assignment can be discussed. From available history records of specialists in all the medical fields you may choose those candidates best suited to your needs.

Northwestern Mutual Life

Space to be occupied by the Medical Department of the Northwestern Mutual Life Insurance Company of Milwaukee will be used as a means of meeting and becoming better acquainted with the Company's medical examiners from all parts of the country. An invitation is being extended to all its medical examiners in attendance at the Convention to visit Booth 256-M, where a representative of the Medical Department will be present to greet them.

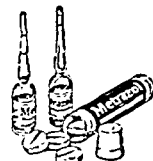

"Evenflo" Baby Nursing Unit

For the third time, the Pyramid Rubber Company will exhibit its "Evenflo" Baby Nursing Units, with valve air-balancing action which prevents vacuum and back pressure. The unit is quickly made ready for feeding and the unit sanitarily protects formula and nipple between feedings. An interesting demonstration will be given at the exhibit, to the left of the main door entrance.

products featured. Aminoacetic Acid (Glycine, Glycocol)-Calco, and various Medicinal Dyes will also be exhibited.

An Aid in the Emergency

At Booth 238, the use of Metrazol to overcome barbiturate or opiate poisoning, surgical shock, and asphyxia, can be discussed. Also the advantages of Dilaudid hydrochloride for pain relief and for cough sedation; Theocalcin, as a diuretic and myocardial stimulant. Other well-known medicinal chemicals exhibited by the Billhuber-Knoll Corporation include Euresol, Lenigallol, and Bromural.

Saftiflasks Demonstrated

Cutter Laboratories, in Booths 212 and 213, will feature their "Council Accepted" biologicals and allied intravenous special-

ties. They will feature their prepared Dextrose Solutions in Saffflasks and the various mechanical improvements and modifications developed during the past year will be demonstrated by competent representatives. Of particular interest will be the Cutter antitoxin syringe.

Sodium Bicarbonate U. S. P.

Church & Dwight Company, Inc., who for 91 years have concentrated on producing pure sodium bicarbonate, will exhibit in Booth 131. Here they will show those venerable and well known products, Arm & Hammer and Cow Brand Bicarbonate of Soda. Representatives will give interesting data on soda products and their manufacture.

Pulvoids—Improved Tablets

The process by which Pulvoids, an improved form of tablet making, was originated in 1913 by the Drug Products Company, Inc., will be demonstrated at Booth 32. A complete price list will be available upon request.

For Diagnostic Help

E. Fougere & Company will offer for your attention, at Booths 168 and 169, the modern approach to diagnosis and treatment offered by Lipiodol radiology. How Lipiodol may often be utilized to obtain more conclusive evidence and visualize pathologic changes will be illustrated and fully described. Descriptive literature will be available.

Striking Display by "Roche"

Hoffman-La Roche, Inc., invites all members of the profession to its striking new display of "Roche" contributions to the cause of scientific medicine, in Booth 63. Here will be an opportunity for personal discussion with the President or heads of the Medical Division, Research Laboratories, and other departments. Particular attention is invited to that part of the exhibit reflecting the pioneer work done by "Roche" in the field of chemically pure crystalline vitamins.

Intravenous Solutions

Intravenous solutions in Filtrair Dispensers will be displayed in Booth 104 by Hospital Liquids, Inc. Capable representatives will be there to discuss the various problems of parenteral therapy. In addition to the regular hospital package, a physician's package, completely sterile and ready for use, will be shown.

Mercurochrome Exhibit

Hynson, Westcott & Dunning, Inc., will have an exhibit featuring Mercurochrome and various other pharmaceuticals of their manufacture. There will also be a display of some of the diagnostic apparatus and ampule solutions which have been developed in cooperation with physicians. As usual, competent representatives of the company will be in attendance to demonstrate the products and to answer questions. Literature and samples will be available to physicians. Booth 239.

House of Vitamins

IVC Corporation will "Council Accepted" Halibut Liver Oil with Vitamin D Concentrate in Neutral Oil—3 minims capsules. Complete information on all matters pertaining to Vitamins will be available for the physician. The Booth number is 256-J.

Ampoule Preparations

Their "Council Accepted" Ampoule preparations, particularly their ampoules of Dextrose (d Glucose) 50%, Sodium Cacodylate and Calcium Chloride, will be exhibited by Lakeside Laboratories, Inc., in Booth 201. Members of the research staff will be present to demonstrate the chemical, bacteriological and physiological methods used to insure the purity, sterility and safety.

Pneumonia Typing Explained

At Booth 102 Lederle Laboratories will feature two of their outstanding products: 1.—"Antipneumococcic Sera Lederle" for use with the Neufeld typing method in pneumonia therapy. 2.—"1 cc. Concentrated Solution Liver Extract Lederle" for intramuscular injection—in secondary and pernicious anemias. A staff lecturer will be on hand to discuss recent dramatic results of the typing method of pneumonia therapy and to illustrate how determination of "type" infection is made. Many other well-known biologicals and pharmaceuticals will be included.

Demonstrations by Lilly

Eli Lilly & Company will have a completely new display occupying Booths 141, 142, 143, and 144. It will feature, among other products, Protamine, Zinc & Iletin (Insulin, Lilly). There will be a continuous demonstration of the Urine Sugar Test Case, Sheftel, designed to give the physician an accurate, portable apparatus for bedside use. Also displayed will be liver products, ephedrine products, biologicals, "Sodium Amytal," "Merthiolate," Carbarsone, and Iletin.

Halibut Vitamin Products

McKesson & Robbins, Inc., of Bridgeport, will display, in Booth 250, a series of halibut liver oil products, accompanied by an exhibit which will indicate the effects and use of vitamins A and D in the treatment of conditions arising from a deficiency of either or both of these vitamins.

Information on Calcreose

At the Maltbie Chemical Company Booth there will be a display of Calcreose, original brand of Calcium Creosote, U. S. P. XI. Any questions you may desire to ask about this product will be answered gladly. You are cordially invited to visit Booth 87.

Cod Liver Oil Research

The Maltbie Company will demonstrate, in Booth 82, the various steps involved in the manufacture of Maltine with Cod Liver Oil, and will show evidence that the vitamin A value of cod liver oil is enhanced two-fold when administered as Maltine with Cod Liver Oil. Charts and illuminated photographs will show results of recent laboratory research on this subject.

A Special Feature by Merck

The Merck display of medicinal specialties, in Booths 162, 163 and 164, will feature long established products as well as some of the most recent chemotherapeutic developments. Among the latter may be mentioned Cebione—Cevitamic Acid Merck, Pure Crystalline Vitamin C. Among the former, Ichthyol is outstanding and needs no introduction. Although not used medicinally, a new scientific and variant.

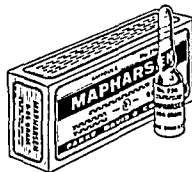

Hormodin "A"—a hormone-like plant growth substance which stimulates rapid root growth on plant cuttings—will be displayed and explained.

Six New Dioramas by Merrell

The Wm. S. Merrell Company will show for the first time in Atlantic City their recently constructed display unit and six new dioramas, which should prove both interesting and educational to every member of the Association. Be sure to see this exhibit (Booth 133) and also receive information about Diothane, Natural Sodium Salicylate, Fibrogen, Sperti Process Vio-sterol and other equally interesting medicinal products.

Parke-Davis Exhibit

A number of scientific accomplishments will be displayed by Parke, Davis & Company's staff of expert technical men in charge of Booths 180, 181, and 182. Products of special interest to the medical profession will be shown, including Mapharsen (a recent advance in antisyphilitic therapy), glandular products, including Adrenalin, also Meningococcus Antitoxin, and other biological products.

Sandoz Specialties

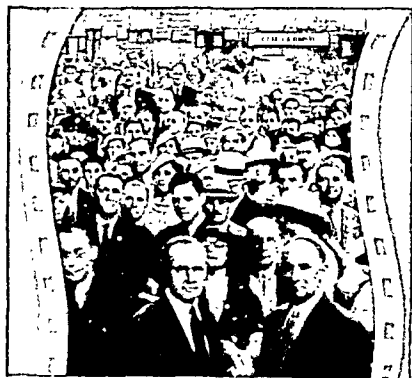

Interesting clinical reports describing the therapeutic advantages of Sandoz specialties may be obtained in Booth 173, where competent representatives will be in attendance. Products to be displayed are: "Gynergen" (Ergotamine Tartrate) for the dramatic relief of migraine and dependable uterine hemostasis; "Calglucon" chocolate flavored tablets, effervescent tablets and granules for oral calcium administration. Other "Council Accepted" preparations to be shown are "Scillaren" "Scillaren-B" and "Sandoptal."

Searle Pharmaceuticals

The rese G. D. Searle & Company Booth 121, a technical Accepted research products. Prominent among these items are Aminophyllin (Searle) and Aqueous Bismuth Sodium Tartrate. A capable staff of Searle representatives will be present, and invite all physicians to review their display and discuss with them any points of particular interest concerning Searle products.

Motion Pictures

Sharp & Dohme will have their new and attractive mahogany-finished display at

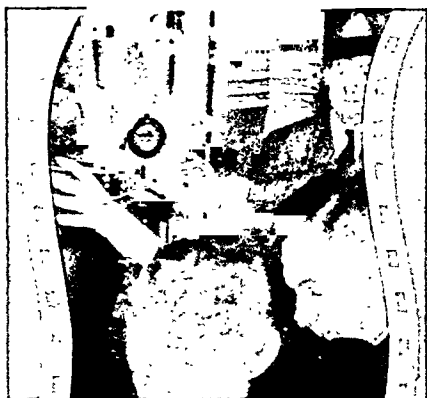

Visitors in Technical Exposition last year at Kansas City.

Booths 95, 96 and 97, where physicians may secure information relative to their extensive line of pharmaceuticals as well as Mulford biologicals. A major attraction will be miniature displays illustrating the processing of pharmaceutical and biological products. Motion pictures will also be in evidence.

Hospitality by Petrolagar

Two new convention displays, new literature and the usual air of hospitality await the doctors at Petrolagar Booths 213 and 48. You are especially invited to take advantage of the comfortable resting space provided for visiting doctors. Competent representatives will be pleased to supply information and literature concerning the use of Petrolagar in the specialized treatment of constipation.

"No Sales Resistance" Needed

At Booths 189 and 190, no sales resistance will be needed. Smith, Kline and French Laboratories, manufacturers of "Benzedrine" and Pentnucleotide, believe that many physicians dislike efforts to get them to register. The booth has therefore been arranged for self-service. The physician may help himself to literature from convenient literature-dispensers, without being urged to leave his name. Yet the attendants are always ready to answer questions and to give out samples of "Benzedrine Inhaler."

Squibb Products to Be Shown

Physicians attending the Meeting are cordially invited to visit the Squibb Exhibit in Booths 148, 149 and 150, where the complete line of Squibb vitamin, glandular, arsenical and biological products and specialties will be on display. A number of interesting new items will be featured, including Protamine Zinc Insulin. Well informed Squibb representatives will be on hand to welcome you and to furnish any information desired on the products displayed.

Facts on Nasal Congestion

At Booth 160 representatives of Frederick Stearns & Company will be glad to discuss recent advances in the treatment of diabetes mellitus. They will also welcome the opportunity to discuss the treatment of nasal congestion. An interesting display of Insulin and Neo-Synephrin will be presented. All physicians are invited to call at the Stearns Exhibit, where they will find competent representatives.

* List of Exhibitors

Firm Name	Aisle	Space No.
Spencer Lens Co.	J.	10
Squibb & Sons, E. R.	E.	148-149-150
Standard X-Ray Co.	I.	49-50
Stearns & Co., Fredk.	E.	160
Sterisol Ampoule Corp.	C.	202
Stokely Bros. & Co.	H.	85
Storz Inst. Co.	F.	124
Sun-Rayed Co.		
Surgical Pub. Co.	G.	106
Tampax Inc.		260
Taylor Instr. Cos.	C.	212

Riedel-de Haen Exhibit

Exhibit of Riedel-de Haen, Inc., will be primarily devoted to Decholin and Decholin-Sodium. The complicated steps in the purification and detoxification of Decholin will be demonstrated and copies of the brochure, "Biliary Tract Disturbances," will be available. If you are interested in the important subject of biliary tract disorders don't miss Booth 171. Also shown will be Pernoston, a safe and dependable hypnotic.

Sterisol Ampoules

The Sterisol Ampoule Corporation will offer, in Booth 202, their various sterile dextrose and saline solutions hermetically sealed in Pyrex brand glass ampoules. The convenience of having safe solutions always available in any desired strength for intravenous or clysis infusions is now generally recognized, and the Sterisol Ampoule is designed to make these administrations simple and secure.

Puritan Maid Products

The Puritan Compressed Gas Corporation, pioneer medical gas manufacturers, will exhibit in Booth 26. The firm manufactures the "Puritan Maid" brand of nitrous oxide, ethylene, oxygen, carbon dioxide, and carbon dioxide-oxygen mixtures, and are also distributors of leading makes of oxygen tents, nasal catheter outfits, and anesthetic apparatus.

Upsher Smith Products

In Booth 43, adjoining Lounge on Aisle I, Upsher Smith Company will feature Pyrethrum Ointment, a "Council Accepted" non-irritating scabies treatment, which has a pleasant odor and is clean and easy for patients to use. A cordial welcome will be extended to all physician visitors.

Cod Liver Oil Concentrates

Information covering the entire field of cod liver oil concentration, together with

clinical data and evidence concerning the efficacy of its Liquid, Tablet and Capsule concentrates, as well as of cod liver oil, per se, will be presented by White Laboratories, Inc., in Booth 226. Informative representatives, and descriptive literature, reprints and excerpts will further demonstrate cod liver oil efficacy, and will point out White Laboratories, Inc., contributions in the vitamin A and D field.

Motion Picture on Edema

Physicians visiting Booth 140, of the Winthrop Chemical Company, are assured of interesting information regarding its outstanding line of analgesics, anesthetics, antirachitics, antispasmodics, antisyphilitics, antigonorrheics, diagnostics, diuretics, hypnotics, sedatives, vasoconstrictors, vasodilators, etc. It is suggested that you inquire about the new motion picture, "Edema—Cardiac and Renal," which is loaned free to medical societies, hospital staffs and medical schools.

For Wound Dressing

Wallace & Tiernan Products, Inc., cordially invite you to visit Booth 30, where they will display Azochloramid, an odorless, stainless and relatively non-irritating chlorine germicide distinguished from other chlorine compounds by its exceptional ability, slow liberation of chlorine, ease of application and prolonged bactericidal action. Forms suitable for topical application to virtually all kinds of tissue will be shown and experienced staff members will be on hand.

Glucose and Digitalis Products

At Booths 221 and 222, John Wyeth & Brother will exhibit their ampoules glucose solution and digitalis products, together with many of their large line of U. S. P. and N. F. preparations. A cordial invitation is extended to physicians to visit these booths.

* Physical Therapy and X-Ray

New Contributions to X-Ray

In Booths 215 and 216 will be seen roentgenographic projection of plane sections of the human body with complete elimination of all posterior and anterior obstructions. These are made by means of the Planigraph, manufactured by the Adlanco X-Ray Corporation. The firm will also show a low-voltage X-ray unit for Chaulot Contact Therapy; the smallest shock and ray proof diagnostic X-ray unit, Heliosphere; and the Schliephake Ultra Short Wave unit, Ultratherm.

Short Wave Diathermy

Burdick will show in Booth 94 their latest developments in short wave equipment, distinguished by having a separate long wave circuit for electrosurgery. Other physical therapy equipment included in the exhibit will be a complete line of ultra-violet and infra-red lamps, suction-pressure equipment and low-voltage generators.

Three Types of X-Ray Films

Agfa Ansoco Corporation will exhibit Agfa High-Speed X-Ray Film for use in usual radiographic technique, Agfa Non-Screen Film for use in cardboard holders, and Agfa Direct Duplicating Film, which makes possible duplicate radiographs in

one photographic step. Agfa clinical photographic materials and equipment will also be on display in the same space. Booth 256-I.

Illuminated Instruments

Cameron Surgical Specialty Company will demonstrate in Booth 19 their latest developments in electrically lighted instruments for surgery and diagnosis. The Tele-Vaginalite will be included. Of special interest will be the new and inexpensive Cameron Cauterodyne for providing safe cutting, coagulation, desiccation and fulguration.

An Early De Forest Audion

"Great oaks from tiny acorns grow!" Lee De Forest Laboratories will exhibit in Booth 111 the 3 electrode vacuum tube with which Dr. Lee De Forest demonstrated to the Bell Telephone engineers his electron telephone relay. By means of it, the first transcontinental long distance telephone line was opened in January 1915. From this little tube has grown the powerful oscillator tube used in modern short wave tube diathermy emitters.

Drinker-Collins Respirator

How the care of severely paralyzed "polio" patients can be greatly improved by the Drinker-Collins Respirator will be demonstrated by the Warren E. Collins Company, Inc., in Booth 62. Another Inter-

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - Seven dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MAY 8, 1937

THE ANNUAL SESSION

The last annual session of the American Medical Association held in Atlantic City was the greatest in attendance of any medical meeting ever held anywhere in the world. More than 8,000 physicians registered their presence, as well as thousands of exhibitors, wives of physicians and others. The illustrations published elsewhere in this issue of THE JOURNAL are an indication not only of this tremendous gathering but also of the extraordinary facilities which Atlantic City supplies to a convention of this character. The technical and scientific exhibits, as well as all the scientific sections, are comfortably housed in the immense auditorium that is a feature of the "Convention City." Moreover, the great hotels that front on the ten mile boardwalk along the ocean yield accommodations suitable to every purse and of exceptional quality.

Atlantic City makes available every type of facility necessary for combining a vacation with attendance at a meeting. Golf, fishing, motoring, sailing and all the innumerable amusements of the great piers, which extend far out into the ocean, are unparalleled in any other single city in the world. Finally, the easy accessibility of Atlantic City to great numbers of physicians forecasts another great session in that city. The special features provided for this year include not only a special session on the subject of the diagnosis, treatment and prevention of syphilis, a subject now prominent in the medical perspective, but also the first exhibition of the talking motion picture clinic on this subject, prepared jointly by the American Medical Association and the United States Public Health Service. Moreover, two great clinical sessions on a variety of subjects will be featured on Monday and Tuesday.

The announcements that have already been received of meetings of associated medical organizations, fraternities, alumni associations, editorial groups, historical societies and similar bodies reveal with certainty that the annual session of the American Medical Association has come to be the outstanding medical event each year in this country. The physician who fails to avail him-

self of the educational features offered by this meeting loses an invaluable opportunity of bringing himself abreast of medical progress and of hearing at first hand the leaders in many fields of investigation.

CALCIUM THERAPY IN DENTISTRY

Efforts to promote the use of compounds of calcium and phosphorus in medicine and in dentistry have been increasing. The representations seem to depend on the assumed deficiency of calcium and phosphorus in the diet and on the assertion that the general ingestion of calcium phosphate compounds is beneficial in overcoming conditions presumably due to what is glibly called calcium imbalance.

Because of the extensive promotion of these products to the dental profession, the Council on Dental Therapeutics, a body analogous to the Council on Pharmacy and Chemistry, has reviewed the functions, uses and actions of calcium in human physiology and nutrition.¹ The Council on Dental Therapeutics points out that the dentist is primarily interested in the following special aspects of calcium metabolism: 1. Are disorders of the teeth, notably dental caries, related to the dietary intake of calcium (and phosphorus)? 2. Is the development of sound teeth in utero dependent on a high intake of calcium during pregnancy? 3. Is there a calcium drain on the mother during pregnancy and lactation, and, if so, is this drain related to the carious process?

The interest of obstetricians, pediatricians and general practitioners in these questions is no less than that of dentists, for they are frequently asked similar questions. The dental council pointed out that there is no direct positive evidence from either the laboratory or the clinic that the addition of calcium and phosphorus compounds to an otherwise ample diet influences in any definite manner the incidence of dental decay in the child or in the adult, or that it promotes the development of noncarious teeth in utero, in infancy and during growth or in the adult; nor is there any sound evidence that a calcium drain during pregnancy and lactation is lessened by the addition of these compounds when the diet is well balanced.

The late Alfred F. Hess² concluded from a roentgenographic examination and chemical study of the teeth of infants from birth onward that: 1. Calcification must be regarded as a postnatal phenomenon. 2. At birth, only 0.5 Gm. of tricalcium phosphate has been laid down in the teeth of both jaws. 3. As far as the teeth of the infant are concerned, it cannot be of great moment whether throughout pregnancy a woman has a diet high in calcium and phosphorus. She is provided with a bounteous storehouse of these substances in the bony skeleton, from which, with the greatest facility and

1. Calcium and Phosphorus Compounds in Dentistry, J. Am. Dent. A. 23: 139 (Jan.) 1936.

2. Hess, A. F.; Lewis, J. M., and Roman, Benjamin: Dent. Cosmos, 74: 1053 (Nov.) 1932.

without the slightest harm to the prospective mother, the 0.5 Gm. required for the denture of the fetus can be withdrawn. 4. The postnatal period is of great significance as regards calcium and phosphorus requirements of the teeth. 5. Little is gained, so far as fetal dentition is concerned, by increasing the calcium and phosphorus intake of the expectant mother.

Macy³ and her collaborators adduced evidence to show that a large intake of vitamin D during the period of pregnancy was of greater importance than added supplies of calcium and phosphorus to a diet.

While there is some dispute as to the exact importance of vitamin D or factors simulating it, the Council on Dental Therapeutics has resolved the problem for dentists by pointing out that cod liver oil has a favorable influence on the absorption and subsequent deposition of calcium and phosphorus in the bones and in the teeth. Consequently cod liver oil is considered among the medicinal foods which, because of their vitamin content, apparently have a beneficial effect on the development of teeth and aid in prophylaxis against dental caries. Accordingly, it lists in its book of accepted dental remedies several brands of cod liver oil and compounds related to it.

Because of the assertions made by certain promoters of so-called organically combined calcium or phosphorus compounds, the Council reminded its readers of the statement of the late Lafayette B. Mendel, made years ago, that the once debated question of superiority of calcium and phosphorus and iron when furnished in some organic form or combination no longer excites interest. This is as real today as when it was first said.

After a careful review of the critical evidence available, the Council concluded that:

1. All the calcium and phosphorus requirements for average needs, including pregnancy and growth, may be suitably obtained by means of an adequate diet containing not only calcium and phosphorus compounds but also other necessary factors, such as caloric, protein and other mineral and vitamin requirements.

2. There is no carefully controlled evidence that the addition of calcium and phosphorus compounds, whether inorganic or organic, promote retention of these elements and hence freedom from dental diseases, except in known cases of deficiency. Where this occurs, milk serves as an excellent source of calcium and phosphorus in a readily assimilable form.

3. There is no evidence that the ingestion of combinations of calcium and phosphorus in addition to diets adequate in these elements promotes the development of sound teeth in the human fetus. The calcification of the teeth is a postnatal event.

The Council emphasized the following statements: "The reparative treatment of dental caries, based on the principle of local susceptibility, depending on dental conformation and natural hygiene, is invariably success-

ful when properly practiced, in that dental caries does not recur under or at the margins of properly treated and filled cavities. Hygienic measures as now applied are probably of definite but limited value in combating caries. Empirical prophylaxis by regulation of the diet of children is distinctly effective, and, at least until the problem becomes more fully understood, deserves more universal adoption."

POTENTIAL HAZARDS OF THE DIAGNOSTIC USE OF THORIUM DIOXIDE

Several years ago, colloidal preparations of thorium dioxide were introduced into medicine for use in radiography.¹ Thorium is opaque to roentgen rays and throws a deep shadow in roentgenograms. It was found that thorium dioxide sol could be introduced into body cavities and even into the blood stream with little immediate deleterious effect. When injected into a vein, the particles are picked up by the reticulo-endothelial system, especially in the liver and spleen, where the material remains indefinitely; the compound thus serves to make these organs less penetrable to the x-rays. Other structures can be visualized by direct injection of thorium dioxide sol into their cavities; these include the cerebral ventricles, the urinary tract, the uterus and fallopian tubes and various accessible blood vessels.

The immediate utility of colloidal thorium dioxide preparations has tended to obscure an important characteristic of this substance: its radioactivity. Over four years ago the Council on Pharmacy and Chemistry¹ pointed out the possible deleterious effects of such a radioactive substance and declined to accept one of these preparations for intravenous injection. The hazard is particularly great when thorium dioxide sol is so administered that the material remains in body tissues for long periods. Because patients who have received injections of this compound have shown no apparent ill effects over a period of several years, some clinicians have concluded that the preparation is safe and have begun to employ it with less caution. It is important to remember, however, that degradation products of thorium emit alpha rays more penetrating than those of the radium series and that this ray is about 10,000 times as toxic to tissues as the gamma ray which is used therapeutically; the alpha rays are filtered out in the therapeutic use of radium and their effects are seen only when the material comes into direct contact with tissues as on ingestion or injection. An amount commonly used for intravenous injection of one of the commercial preparations of thorium dioxide has an alpha ray activity equivalent to that of from 1.5 to 3 micrograms of radium. Surely physicians would hesitate to inject the latter quantity of radium into a patient's vein!

Experience with radioactive intoxications indicates that as much as ten or fifteen years (and perhaps

3. Macy, Icie G.; Hunscher, Helen A.; McCosh, Sylvia S., and Nims, Betty: J. Biol. Chem. 56: 59 (March) 1930.

1. The literature is reviewed in a Preliminary Report of the Council on Pharmacy and Chemistry: Thorotrast, J. A. M. A. 99: 2183 (Dec. 24) 1932.

longer) may elapse between ingestion of the active material and the onset of gross tissue changes. The fact that patients who have been injected with thorium dioxide have shown no detectable toxic effects from the substance over a period of a few years is not satisfactory ground for complacency as to ultimate results. Recent reports, on the contrary, emphasize the proclivity of this substance to produce necrosis and malignant change² in tissues with which it remains in contact.

The danger of the internal use of long-lived radioactive substances has been amply demonstrated in past experience. Investigators versed in this matter have repeatedly pointed out that these materials should never be so administered as to remain in the human body for long periods.

Current Comment

THE MOTION PICTURE ON SYPHILIS

In connection with recent emphasis on syphilis as a public health problem, the American Medical Association, by action of its Board of Trustees, and the United States Public Health Service have jointly engaged in the production of a clinic on syphilis in a talking motion picture. The picture is now being made by the Burton Holmes organization in Chicago; it is expected that it will be available for a first showing at the annual session of the American Medical Association to be held in Atlantic City. After a preliminary announcement in the picture by Surgeon General Thomas Parran and President Charles Gordon Heyd, the diagnosis of syphilis is covered by Dr. John H. Stokes of Philadelphia. Latent syphilis is discussed by Dr. Paul A. O'Leary of Rochester, Minn., the treatment of syphilis by Dr. Harold N. Cole of Cleveland, late syphilis by Dr. Joseph E. Moore of Baltimore, syphilis in pregnancy by Dr. James R. McCord of Atlanta, Ga., syphilis in the child by Dr. Philip C. Jeans of Iowa City, and the public health aspects of syphilis by Dr. Raymond A. Vonderlehr of the United States Public Health Service. The technic of taking blood for a Wassermann test, spinal fluid examination and intravenous injection are shown. The systematic technic of treatment is revealed not only on patients but also diagrammatically. It is hoped to provide with the picture a reprint of the main points brought out so that those who attend may carry away a permanent reference to the significant information. When the picture is completed, copies will be made available to state and county medical societies, hospital conferences and other assemblages of physicians.

GARLIC VAPOR AS A BACTERICIDAL AGENT

One of the curiosities of recent bacteriologic research is confirmation of the popular superstition that onion and garlic vapors are efficient bactericidal agents. Vollrath, Walton and Lindegren¹ of the University of Southern California have provisionally identified the volatile bactericide in garlic as allyl aldehyde. This is not one of the substances giving garlic its characteristic odor. The California bacteriologists found that when an agar plate is exposed to the vapors of freshly crushed garlic for thirty minutes a sufficient amount of volatile bactericide is absorbed by the agar to kill all bacteria in a heavy suspension of *Escherichia coli* streaked on the surfaces immediately after exposure. In order to identify this volatile antiseptic they synthesized and tested separately or in combination the various volatile components known or believed to be present in garlic. Methyl sulfide, ethyl sulfide, ethyl disulfide and allyl disulfide, the other oils giving the characteristic odor, were found to be ineffective. Allyl alcohol was also ineffective, but allyl aldehyde ("acrolein") had a volatile bactericidal index equal to that of crushed garlic. In vitro tests showed that a 1:10,000 aqueous solution of "acrolein" would sterilize a *Bacillus coli* suspension within forty-eight hours and that in this dilution the aldehyde is equally effective in the presence of proteinaceous material (egg white). In the absence of egg white, "acrolein" is an effective bactericide in dilutions as high as 1:10,000,000. Lewin³ had previously shown that "acrolein" is relatively non-toxic for mammals, the lethal dose being in the neighborhood of 0.25 Gm. per kilogram of body weight.

BRITTLE BONES AND BLUE SCLERAS

Occasionally, clinicians or investigators encounter a rare or unusual clinical entity which, because of its infrequent occurrence, is worthy of detailed examination. The so-called inborn errors of metabolism may be considered among these extraordinary conditions. These comparatively rare clinical entities frequently have a hereditary aspect. This is true of the syndrome of brittle bones and blue scleras. The pathology and hereditary features of this disease have been comprehensively treated by Key¹ and by Bell.² Recently a report of another case, including a family history of five generations, has been reported in detail.³ A white girl, aged 10 years, was concerned and data were gathered on fifty-one other members of the same family. The family tree shows the appearance of characteristic signs of the syndrome in twenty-seven of the fifty-one family members. The disease follows the mendelian laws of inheritance, appearing as a dominant character. Four distinct features characterize this clinical entity: blue scleras, fragile bones, a tendency to deafness and marked relaxation of the ligaments. The authors pre-

sent a detailed consideration of the etiology, pathologic changes and treatment in the case under observation. Although the rarity of the disease may make it a clinical curiosity, this ample account is a valuable contribution to the few available data regarding this syndrome.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

State Medical Meeting and Election.—Dr. Sidney J. Wolfermann, Fort Smith, was chosen president-elect of the Arkansas Medical Society at its annual meeting in Little Rock, April 12-14, and Dr. Oscar J. T. Johnston, Batesville, was inducted into the presidency. Vice presidents are Drs. Herbert Fay H. Jones, Little Rock; Joseph F. John, Eureka Springs, and Logan C. McVay, Marion. Drs. William R. Brooksher, Fort Smith, and Royal J. Calcote, Little Rock, were reelected secretary and treasurer respectively. The next annual meeting will be held in Texarkana. Included on the program were the following guest speakers:

Dr. Charles Gordon Heyd, New York, President, American Medical Association, Recognition and Treatment of Peritonitis.
Dr. Charles B. S. Evans, Los Angeles, Sterility.
Dr. Byrl R. Kirklin, Rochester, Minn., Cholecystography as an Aid to Diagnosis.
Dr. Theodore A. Watters, New Orleans, Anxiety States.
Dr. Harry W. Lyman, St. Louis, Lateral Sinus Thrombosis.
Dr. Roy R. Kracke, Emory University, Ga., Role of Drugs in the Production of Agranulocytosis.
Dr. Charles H. Eyermann, St. Louis, The Applicability of Allergy to General Practice.
Dr. Harry Wilkins, Oklahoma City, Craniocerebral Injuries.
Dr. Joseph Hoy Sanford, St. Louis, What the Practitioner Should Know About Urology.

The woman's auxiliary held its thirteenth annual meeting during the session of the state medical association.

CALIFORNIA

The Abortion Syndicate.—The California State Board of Medical Examiners reports that the California licenses of the following physicians have been revoked for their part in the Pacific Coast "abortion ring": Jesse C. Ross, Los Angeles, who graduated from the St. Louis College of Physicians and Surgeons in 1910; Alfred Henry Valentine St. John, Los Angeles, who is a licentiate of the Royal College of Physicians of London and a member of the Royal College of Surgeons of England, 1908; James H. Beggs, Glendale, who graduated from the College of Physicians and Surgeons, Los Angeles, in 1917, and George Eliot Watts, Los Angeles, who graduated from the University of Oregon Medical School, Portland, in 1895. According to the newspapers the abortion ring was organized so that its physicians rotated in the various cities at frequent intervals to avoid becoming well known. The syndicate was alleged to net \$1,000,000 annually. The "Medical Acceptance Corporation," an outgrowth of the syndicate's operations, was patterned after automobile finance agencies, so that part payments with rates of interest appropriate under the circumstances might be secured for some of the patients.

DISTRICT OF COLUMBIA

Course in Ophthalmology.—George Washington University School of Medicine, Washington, will sponsor a course in ophthalmology, May 31-June 5. In addition to the members of the department of ophthalmology, the following guests will participate: Drs. Clyde A. Clapp, Baltimore; Arthur J. Bedell, Albany, N. Y.; Sylvester Judd Beach, Portland, Maine; Conrad Berens, New York; Harry S. Gradle, Chicago; Sanford R. Gifford, Chicago; Le Grand H. Hardy, New York; Patrick Chalmers Jameson, Brooklyn; Edward Jackson, Denver; Daniel B. Kirby, New York; Samuel Hanford McKee, Montreal, Que., Canada; Walter B. Lancaster, Boston; Edmund B. Spaeth, Philadelphia, and Robert Von der Heydt, Chicago. One afternoon will be spent at the Army Medical Center and another afternoon at the National Bureau of Standards, where allied problems in the field of physics and optics will be discussed.

ILLINOIS

State Medical Meeting at Peoria, May 18-20.—The eighty-seventh annual meeting of the Illinois State Medical Society will be held in Peoria, May 18-20, with headquarters at the Pere Marquette and under the presidency of Dr. Rolland L. Green, Peoria. The oration in medicine will be delivered Tuesday afternoon by Dr. Virgil E. Simpson, Louisville, Ky., on "Abdominal Visceral Pain: A Physiological and Clinical Consideration," and the oration in surgery by Dr. Vilray P. Blair, St. Louis, Wednesday morning, May 19, on "Early Treatment of Injuries of the Face and Jaws." Other out-of-state speakers will include Drs. Robert J. Masters, Indianapolis, on "Lesson Learned from Blind School Survey," and French K. Hansel, St. Louis, "Allergy of the Upper Respiratory Tract and Its Relation to Other Manifestations." The program will also include symposiums on acute infectious diseases and pneumonia, the latter to be presented at the pediatricians' meeting Tuesday morning. Others on the program will include:

Dr. M. Herbert Barker, Chicago, Dangers of Rapid Diuresis in the Cardioresenal Vascular Patient.
Drs. Italo F. Volini and William W. Shapiro, Chicago, Malaria with Special Reference to Narcotism.
Dr. Perry J. Melnick, Decatur, Pulmonary Changes in Rheumatic Fever.
Dr. Robert E. L. Gunning, Galesburg, Bile Peritonitis with Case Report.
Dr. Milton H. Kronenberg, Chicago, Industrial Hygiene—Its Historical Development and the Modern Campaign.

The annual secretaries' conference will be held Tuesday morning with the following speakers:

Dr. Green, Retrospect and Prospect.
Dr. Harold M. Canup, Monmouth, Correlation of Secretarial Duties in the State Medical Society.
Mr. John Beineman, Oak Hill, chairman of board of supervisors of Peoria County, How May the County Medical Society Aid in Township Relief?
Dr. John R. Neal, Springfield, State Medicine.
Dr. Robert H. Hayes, Chicago, Socialized Medicine.
Miss Jean McArthur, Chicago, What the Education Committee Does for County Medical Societies.

Entertainment Tuesday evening includes the stag dinner, with the Peoria Medical Society acting as host, and the veterans' service committee dinner. At the annual president's dinner, in honor of Dr. Green, Wednesday evening, all living past presidents of the society will be guests. The woman's auxiliary will have its headquarters at the Jefferson Hotel. The Central States Society of Industrial Medicine and Surgery will convene in annual session Tuesday and speakers at a joint session with the surgical section of the state medical society will include Dr. Reginald M. Carter, Green Bay, Wis., on "Pellegrini-Stieda's Disease" and Mr. Edward W. Rawlins, Chicago, "Malpractice in Relation to Industrial Surgery."

Chicago

Dr. Erich Hoffmann Lectures on Syphilis.—Dr. Erich Hoffmann, professor of dermatology and syphilology, University of Bonn, Bonn, Germany, co-discoverer of *Spirochaeta pallida*, will lecture on syphilis at the University of Illinois College of Medicine, May 11, from 4 to 5 p. m., in room 423. Members of the Chicago Medical Society are invited.

Dr. Wakerlin Appointed Professor of Physiology.—Dr. George E. Wakerlin, professor of pharmacology and physiology, University of Louisville School of Medicine, Louisville, Ky., has been appointed professor and head of the department of physiology at the University of Illinois College of Medicine, effective September 1. Dr. Wakerlin will succeed Dr. Maurice B. Visscher, who resigned to accept a position at the University of Minnesota School of Medicine as professor and head of the department of physiologic chemistry in September 1936. Dr. Wakerlin, who is 35 years of age, graduated from Rush Medical College in 1929.

Annual Orthopedic Meeting.—The fourteenth annual meeting of the Chicago Orthopaedic Society will be an all day session, May 14. Two memorial plaques to Jane Neil, for many years head of the Spalding School for Crippled Children, will be presented, one to the school and another to the Janell Shop, at ceremonies to be held at the school in the morning. The presentation of the first will be made by Dr. John L. Porter and the speech of acceptance by Miss Thecla Doniat, present head of the school. Dr. Edward L. Ryerson will present the second plaque, and Mrs. Morris Fishbein will deliver the speech of acceptance. "Personal Recollections of Jane Neil" will be offered by Mrs. Rose Rudolph, a former teacher. Miss Neil died Oct. 29, 1932. A clinic will be held at Cook County Hospital from 1:30 to 2:30 p. m. by Drs. Sumner L. Koch and Michael L. Mason on "Infections and Disabilities of the Hand." In the evening there will be a dinner at the Palmer House with Dr. Albert H. Freiberg, professor of ortho-

pedic surgery, University of Cincinnati College of Medicine, Cincinnati, as toastmaster. Speakers at the dinner meeting will be:

Dr. Lewis J. Pollock, Diagnosis of Peripheral Nerve Injuries.
Dr. Alfred W. Adson, Rochester, Minn., Surgical Treatment of Peripheral Nerve Injuries.
Dr. Willis C. Campbell, Memphis, Tenn., Treatment of Recent, Ununited and Malunited Fractures of the Shaft of the Femur.
Dr. Freiberg, Orthopedic Surgery in the Light of Its Evolution.

KANSAS

Mental Hygiene Conference.—Bert A. Nash, Ph.D., professor of psychology, University of Kansas, was reelected president of the Kansas Society for Mental Hygiene at its annual conference in Wichita, April 9-10. Other officers are Dr. Ralph M. Fellows, superintendent, Osawatomie State Hospital, vice president; Dr. Joseph Stanley Reifsnider, Wichita, treasurer, and Wilbert J. Mueller, Wichita, president, Sedgwick County Society of Mental Hygiene, executive secretary. The speakers at the session included Dr. George Douglas Gordon Campbell, Chicago; Chauncey M. Louttit, Ph.D., Indianapolis, and Dr. Henry H. Turner, Oklahoma City.

LOUISIANA

New Director of Tuberculosis Control.—Dr. Reuben A. Brown has been appointed director of tuberculosis control of the state department of health. A native of Texas, Dr. Brown graduated from University of Pennsylvania School of Medicine in 1928. He has been associated with the Alabama department since 1932, except for a few months when he was identified with the Georgia State Sanatorium at Alto.

Dr. Nelson to Head Department of Pharmacology.—Dr. Erwin E. Nelson, professor of pharmacology, University of Michigan Medical School, Ann Arbor, has been appointed head of the department of pharmacology at Tulane University of Louisiana School of Medicine, New Orleans, succeeding Dr. John T. Halsey, who is retiring at the close of the present session, it is reported. Dr. Nelson obtained the degree of doctor of philosophy at the University of Missouri in 1920 and the medical degree at the University of Michigan in 1926. He was assistant in zoology at Missouri from 1913 to 1916 and assistant professor of pharmacology at Michigan from 1919 to 1927, when he was named associate professor. He was pharmacologist to the U. S. Department of Agriculture from 1923 to 1924 and again in 1927, and in 1931 consultant to the Food and Drug Administration. In January 1935, under a leave of absence from the University of Michigan, Dr. Nelson was designated principal pharmacologist in charge of the drug division of the Food and Drug Administration (THE JOURNAL, Feb. 23, 1935, p. 663). Following his organization of the division he returned to Michigan, Oct. 1, 1936, as professor of pharmacology. Dr. Halsey first became associated with Tulane in 1901 as lecturer in pharmacology. He was professor of materia medica and therapeutics from 1904 to 1912, when he became professor of pharmacology and therapeutics. He has been professor of pharmacology since 1927. He was born in Elizabeth, N. J., in 1870, and graduated from Columbia University College of Physicians and Surgeons, New York, in 1893.

MARYLAND

Dr. Adolf Meyer Honored.—Dr. Adolf Meyer, Henry Phipps professor and director of the department of psychiatry, Johns Hopkins University School of Medicine, Baltimore, was guest of honor at a meeting at Johns Hopkins Hospital, April 16-17. The meeting celebrated his completion of forty-four years of psychiatric work in the United States and of twenty-seven years as head of the department of psychiatry at the medical school. Papers were presented by Drs. Oskar Diethelm, New York; Louis Hausman, New York; Edward J. Kempf, Wading River, N. Y.; Leslie Hohman, Baltimore; Frederic Wertham, New York, and Frederick H. Allen, Philadelphia. The program also included a reunion of former staff members of the Henry Phipps Psychiatric Clinic, which is now entering its twenty-fifth year. As a special tribute to the occasion, the *Archives of Neurology and Psychiatry* for April was dedicated to Dr. Meyer, who is a member of the editorial board. Born near Zurich, Switzerland, Dr. Meyer took his medical degree at the University of Zurich Faculty of Medicine in 1892. He served as honorary fellow at the University of Chicago and later as docent in neurology from 1892 to 1895. During the ensuing years until 1910, when he became affiliated with Johns Hopkins, he was associated with the Kankakee (Ill.) State Hospital; Worcester (Mass.) Insane Hospital;

Clark University; Pathological Institute, New York State Hospitals, and Cornell University Medical College. In 1908 Dr. Meyer was appointed professor of psychiatry at Johns Hopkins but did not actually take up his duties there until 1910. The Phipps Clinic was built under his supervision during the period 1911-1913. He has been president of several scientific societies, including the American Neurological Association, American Psychiatric Association, New York Psychiatric Society and American Psychopathological Association.

MICHIGAN

Institute on Child Health.—The ninth annual child health institute sponsored by the J. L. Hudson Company, Detroit, was held March 8-13. Members of the Wayne County Medical Society participated in the program:

Dr. Harold C. Mack, Modern Maternity Care and Its Problems.
Dr. Russell W. Alles, Maternity—A Few Facts and Fallacies.
Dr. Clarence H. Eisman, Safeguarding Your Baby's Health.
Dr. Donald J. Barnes, The Feeding and Management of Your Baby.
Dr. Henry A. Luce, The Mental Health of the Parent at Forty.

Other speakers included Drs. Thurman B. Rice, Indianapolis, on "The Problems of Adolescence"; William E. Blatz, Toronto, Canada, and Allan R. Dafoe, Callander, Ont. The woman's auxiliary to the county medical society acted as hostesses during one day of the institute.

Society News.—At a meeting of the West Side Medical Society in Detroit, April 1, the speakers included Drs. John E. Gleason on "Malignant Exophthalmos in Exophthalmic Goiter" and Roger S. Siddall, "Care of the Postpartum Cervix—Its Relation to Malignancy."—Dr. Derrick T. Vail Jr., Cincinnati, discussed "Ocular Aspects of Unusual Pituitary Disorders" before the Wayne County Medical Society, Detroit, April 5. The society was addressed, April 19, by Thomas B. Fletcher, M.B., associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, on the endocrine glands.—Dr. Wilber E. Post, Chicago, discussed "Recent Advances in Diagnosis and Treatment of Medical Kidney Disease" before the Kalamazoo Academy of Medicine, March 16.—The Upper Peninsula Medical Society will hold its annual meeting in Houghton, August 19-20.—Dr. Albert D. Ruedemann, Cleveland, discussed "Headache and Head Pain" before the Bay County Medical Society at Frankenmuth, March 10.—Dr. Willard Van Hazel, Chicago, discussed empyema before the Muskegon County Medical Society in Muskegon, March 25.

MISSISSIPPI

State Medical Meeting at Meridian, May 11-13.—The seventieth annual session of the Mississippi State Medical Association will be held at the Convention Hall, Meridian, May 11-13, under the presidency of Dr. Harvey F. Garrison, Jackson. Out-of-state speakers include:

Dr. Joseph Brennemann, Chicago, The Acute Abdomen in Children.
Dr. Paul Holinger, Chicago, Diagnosis and Treatment of Diseases of the Esophagus.
Dr. Walter C. Alvarez, Rochester, Minn., Helpful Hints in the Diagnosis of Gastro-Intestinal Diseases.
Drs. Seale Harris and Seale Harris Jr., Birmingham, Ala., Diagnosis, Dietary Management and Treatment of Gastric and Duodenal Ulcers by the General Practitioner.
Dr. Murdock S. Eguen, Atlanta, Ga., Bronchoscopy as an Aid to Diagnosis.
Dr. Willis C. Campbell, Memphis, Tenn., Present Status of Fractures of the Neck of the Femur.
Dr. Daniel C. Elkin, Atlanta, Thyroidectomy: Factors Influencing Mortality.
Dr. James B. Costen, St. Louis, Summary of the Neuralgias and Ear Symptoms Associated with the Mandibular Joint.
Dr. Raymond A. Vonderlehr, Washington, D. C., The Private Physician's Part in the Control of Syphilis.
Dr. Hiram W. Kostmayer, New Orleans, Postgraduate Medical Education.
Dr. Virgil L. Payne, Pine Bluff, Ark., The Modern Concept of Sinus Surgery versus the Idea Once a Sinus Always a Sinus.

Round table discussions will be led by Dr. Eguen on "Diagnosis of Bronchoscopy and Esophagoscopy" and by Dr. Costen on "The Sluders Syndrome and Its Causes." Dr. William D. Haggard, Nashville, Tenn., will present the Ewing Fox Howard Oration, Tuesday evening, on "What Can Be Done to Cure Cancer?" The fourteenth annual meeting of the woman's auxiliary will be held during the two days. The eighth annual session of the Mississippi State Hospital Association will be held Monday morning May 10.

MISSOURI

St. Louis Clinics.—The annual graduate course and clinical conference of the St. Louis Clinics will be held in St. Louis, May 24-29. Lectures, demonstrations and clinics have been arranged with special reference to the requirements of the general practitioner. Further information may be obtained from the St. Louis Clinics, 3839 Lindell Boulevard, St. Louis.

Executive Secretary for Jackson County.—Mr. Floyd Kenneth Helsby has been appointed to the newly created post of executive secretary of the Jackson County Medical Society. He has been for several years associated with General Mills, Inc., where he was engaged in sales and traffic accounting and sales promotional work. The position of executive secretary of the society has heretofore been on a part time basis.

Public Health Meeting.—The Missouri Public Health Association held its annual meeting at the Kentwood Arms Hotel in Springfield, April 29-30. Speakers included:

- Joseph C. Willett, St. Louis, D.V.M., Certification of Private, Clinical and Public Health Laboratories.
- Dr. Oliver C. Wenger, U. S. Public Health Service, St. Louis, Venereal Disease Program.
- Dr. Joseph D. James, Springfield, Maternal and Infant Welfare.
- Dr. Winfield K. Sharp Jr., New Orleans, regional consultant, U. S. Public Health Service, The Next Step in the Social Security Program as It Relates to Public Health in Missouri.
- Dr. Ellis Fischel, St. Louis, The Cancer Problem in Missouri and How to Meet It.

At the annual banquet Friday evening, Dr. Lynn M. Garner, Tusculumbia, among other speakers, delivered his presidential address.

NEBRASKA

Society News.—Drs. Charles F. Geschickter, Baltimore, and Francis L. Simonds, Omaha, addressed the Omaha-Douglas County Medical Society, Omaha, April 13, on "Chronic Cystic Mastitis and Tumors of the Breast" and "Low Back Pain Due to Herniation or Rupture of the Inner Vertebral Disk Into the Spinal Canal" respectively.—At a meeting of the Northeast Nebraska Medical Society in Wayne, March 11, the speakers were Drs. John Buis, Pender, on "Arsenic Poisoning Traced to Flour"; Frederick W. Niehaus, Omaha, "Coronary Disease," and Rollin Russell Best, Omaha, "Practical Aspects of Lesions of the Colon and Rectum."

State Medical Meeting at Omaha May 10-13.—The annual meeting of the Nebraska State Medical Association will be held in Omaha May 10-13 at the Hotel Paxton. The guest speakers will include:

- Dr. Richard H. Jaffé, Chicago, Diffuse Hepatitis.
- Dr. James R. Reinberger, Memphis, Tenn., The Treatment of Pyelitis as a Complication of Pregnancy.
- Dr. Edgar J. Huenekens, Minneapolis, Breast versus Artificial Feeding.
- Dr. Richard H. Overholt, Boston, Primary Carcinoma of the Lung.
- Dr. Charles Gordon Heyd, New York, President, American Medical Association, Diagnostic Interpretation of Jaundice.
- Dr. Clarence M. Hyland, Los Angeles, The Convalescent Serum Center and Its Value to the Community.
- Dr. Theodore F. Riggs, Pierre, S. D., The Prone and Right Lateral Positions for Gravity Drainage in Perforated Appendicitis.

Drs. Huenekens, Reinberger and Hyland will present a symposium on maternal and child health at the opening meeting Tuesday morning. Dr. Jaffé and Dr. Overholt will be the speakers in a symposium on cancer Tuesday evening and the film "Fight Cancer with Knowledge" will be shown. In a symposium on traumatic surgery Thursday afternoon the guest speakers will be Drs. William R. Cubbins and Harry E. Mock, Chicago. At a luncheon Wednesday Dr. Heyd will speak on "The Spirit of Organized Medicine"; he will also address the woman's auxiliary on "The Woman's Auxiliary and Organized Medicine." There will be a round table luncheon Thursday with Drs. Riggs, Cubbins and Mock as the speakers on traumatism and bone infection. The annual golf tournament will take place Monday May 10 at the Omaha Field Club and a trap shoot has been arranged at the Ak-Sar-Ben Field.

NEW HAMPSHIRE

State Medical Meeting at Manchester.—The one hundred and forty-sixth annual meeting of the New Hampshire Medical Society will be held in Manchester, May 18-19, at the Hotel Carpenter. The program announces the following guest speakers:

- Dr. Ralph E. McDonnell, New Haven, Conn., The Problem of Allergy in Diseases of the Skin.
- Dr. Warren T. Vaughan, Richmond, Va., Recent Advances in the Study of Food Allergy.
- Dr. Charles Gordon Heyd, New York, President of the American Medical Association, Differential Diagnosis of Jaundice.
- Dr. Anton J. Carlson, Chicago, Facts and Fallacies of Organotherapy.
- Dr. Fuller Albright, Boston, Medical Aspects of the Renal Stone Problem.
- Dr. Emanuel Ross Mintz, Boston, The Insidiousness of Certain Cancers of the Urinary Organs.
- Dr. Clyde L. Deming, New Haven, Conn., Treatment of Pyogenic Cystitis.
- Dr. James Dellinger Barney, Boston, Transurethral Prostatic Resection versus Prostatectomy.

At the annual banquet a "fifty year gold medal" will be presented to Dr. Nathaniel H. Scott, Wolfeboro, marking fifty years' membership in the society, and Dr. Henry O. Smith,

Hudson, will receive a silver medal for fifty years of medical practice. Speakers at the banquet will be Governor Francis P. Murphy, Dr. Frank E. Kittredge, Nashua, president of the society, and Dr. Heyd; Dr. Raymond H. Marcotte, Nashua, is chairman.

NEW JERSEY

Unlicensed Practitioners Convicted.—The New Jersey State Board of Medical Examiners recently reported the following activities since the beginning of the year in the prosecution and conviction of unlicensed practitioners of medicine:

Isabel B. Turner, Englewood, pleaded guilty January 14 in the Englewood District Court to a charge of practicing medicine without a license and paid the penalty.

May Lee Clonts, Asbury Park, was found guilty January 20 of practicing medicine without a license and paid the penalty.

Richard Miller, Newark, a naturopath, pleaded guilty February 15 to a charge of practicing without a license.

Stanley J. Bayorek, Irvington, a chiropractor, pleaded guilty February 16 to a charge of practicing medicine without a license.

NEW MEXICO

A Separate State Board of Health.—In accordance with a law enacted at the recent session of the state legislature, a separate board of public health has been appointed, with Dr. Eugene W. Fiske, Santa Fe, as president and Mr. E. P. Moore as secretary. Other members are Dr. Eugene P. Simms, Alamogordo, Dr. Meldrum K. Wylder, Albuquerque, and Mrs. Tobias Espinosa, Espanola, wife of a physician. The law forbids the board to make rules that prohibit any member of the healing arts from signing death certificates. Therefore it is now legal for a chiropractor to sign death certificates, the health department points out.

NEW YORK

Personal.—Dr. Rafael Ernest Lopez, Crestwood, a native of Venezuela who has lived in New York since 1923, has been appointed minister of education in Venezuela, according to the *New York Times*.—Dr. James C. Walsh, superintendent of the Schenectady County Tuberculosis Hospital, Schenectady, has resigned to become superintendent of the Nassau County Sanatorium, Farmingdale. He was to assume the new position April 15.

Changes in State Health Department.—Drs. Archibald S. Dean, Buffalo, and Frank W. Laidlaw, Middletown, have been permanently appointed district health directors on the staff of the state department of health. Dr. Dean has been health officer in charge of Cattaraugus, Chautauqua, Erie, Genesee, Niagara, Orleans and Wyoming counties; Dr. Laidlaw of Orange, Rockland, Sullivan, Ulster and Westchester counties. Both will continue their present positions and will have supervision of health activities in other jurisdictions as well. Dr. Cleland A. Sargent, recently in charge of a syphilis control program in Buffalo, has been appointed a district health officer.

New York City

Personal.—The medical staff of Beth Israel Hospital gave a dinner at the hospital April 25 in honor of Drs. Emil Altman and Ervin Torok, who have announced their retirement from the active staff after many years of service. Both have been appointed to the consulting staff.—Dr. William Seaman Bainbridge has been decorated by the king of Italy with the insignia of Commander of the Order of Saints Mauritius and Lazarus.

City Needs Beds for Tuberculosis Patients.—A minimum of 2,500 more beds for tuberculosis patients in New York is urgently needed, a hospital survey just completed under the direction of Dr. Haven Emerson has revealed. The survey report is now in process of publication. In 1936, there were 4,586 deaths from tuberculosis in New York, 215 more than in 1935. The most liberal provision among large cities in the United States is two beds for each death from tuberculosis in the year, Dr. Emerson pointed out, and the least allowance, one bed for each annual death. New York's tuberculosis hospitals had a normal capacity of 5,184 and the average census during the year was 5,425. An increase of 2,500 beds would give the city a ratio of 1.7 beds per annual death, compared with 2.3 for Detroit, 2 for Milwaukee, 2.1 for Buffalo, and 2.1 for Seattle. The 5,184 beds are in twenty-three hospitals, ten municipal and thirteen voluntary. More than 17,000 patients are admitted to these institutions in a year and spend an average of 111 days in the hospital. Eighty-three per cent of these patients are in the advanced or far advanced stage and fully a fourth of them die in the hospitals. Dr. Emerson said that the aggregate average census year in and year out is not less than 102 per cent of capacity. There are at least as many

more tuberculosis patients in their homes as there are patients in the hospitals. The borough of Manhattan is the most serious challenge. In 1921 its death rate was 130 per hundred thousand when that of the city was 102, and in 1936 it was 121 when that of the city was 62. In the other boroughs the rate has fallen nearly 50 per cent, but in Manhattan only 7 per cent. Dr. Emerson said that, although Negroes make up only 5 per cent of the population of the city, 15 per cent of the tuberculous patients are Negroes and 25 per cent of the deaths occur among them. Among Puerto Ricans the death rate is six times as high as in native white persons.

OHIO

Graduate Course at University of Cincinnati.—A graduate course in otology and rhinology for surgeons specializing in otolaryngology will be offered at the University of Cincinnati College of Medicine May 24 to June 4. Members of the faculty and Dr. Max Halle, New York, will give the instruction. Twenty-five physicians can be accommodated.

Sixtieth Year of Obstetric Society.—The Cincinnati Obstetrical Society celebrated its sixtieth anniversary at a banquet March 18, with Dr. James M. Pierce as toastmaster. Dr. Arthur G. King reviewed the society's history; Drs. Edwin W. Mitchell, a member for fifty-two years, and James W. Rowe, a member for thirty-two years, also contributed reminiscences. Entertainment arranged by Dr. William J. Graf concluded the program. Dr. Gilbert Mombach is president of the society and Dr. Edwin W. Enz, secretary.

Society News.—A symposium on arthritis formed the program of the Sixth District Medical Society in Akron, March 24. The speakers were Drs. Frederick A. Smith and Edward L. Voke, Akron, and William A. McConkey, Canton. Drs. John H. J. Upham, President-Elect of the American Medical Association; John B. Alcorn, president-elect of the Ohio State Medical Association; Herbert M. Platter, secretary of the State Medical Board of Ohio, and Jonathan Forman, editor of the *Ohio State Medical Journal*, all of Columbus, were special guests.—Dr. William F. Braasch, Rochester, Minn., addressed the Toledo Academy of Medicine, March 5, on "Recent Experiences with Ammonium Therapy in Treatment of Urinary Infections."—Dr. Irvin Abell, Louisville, Ky., addressed the Montgomery County Medical Society, Dayton, March 5, on acute conditions in the abdomen.

OKLAHOMA

State Medical Meeting at Tulsa.—The forty-fifth annual session of the Oklahoma State Medical Association will be held in Tulsa May 10-12, at the Mayo Hotel. The guests of honor who will address special sessions are:

Dr. Olin West, Secretary and General Manager, American Medical Association, Chicago, Organized Medicine.
Dr. Charles A. Elliott, Chicago, Management of Cardiovascular Disease; Management of Hepatic Disease.
Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., Syphilis Control.
Dr. James S. Speed, Memphis, Tenn., Present Status of Fractures of the Neck of the Femur; Fractures of the Forearm.
Dr. Elliott will also address the section on general medicine on "Management of Edema" and Dr. Millard F. Arbuckle, St. Louis, will be the guest of the section on eye, ear, nose and throat, speaking on "Diagnosis of Nonopaque Foreign Body in the Lung," and Dr. Joseph V. Van Cleve, Wichita, Kan., of the section on dermatology and radiology, speaking on "Lymphogranuloma Inguinale." Among Oklahoma physicians on the program are:

Dr. Bert F. Keltz, Oklahoma City, The Use of Protamine Insulin.
Dr. Ray M. Balyeat, Oklahoma City, Food Allergy with Special Reference to the Diagnostic Value of the Leukopenic Index.
Dr. David L. Edwards, Tulsa, Ocular Muscle Imbalance Following Head Injuries.
Dr. John R. Cotterall, Henryetta, The Use of Hydrochloric Acid in the Treatment of Asthma in Children.
Dr. Frederick Redding Hood, Oklahoma City, Cardiovascular Syphilis.
Dr. Curt O. von Wedel, Oklahoma City, Revamping the So-Called Unattractive Nose.
Dr. Laile G. Neal, Ponca City, Prevalence of Syphilis in Obstetric Practice.
Dr. Gertrude S. Nielsen, Oklahoma City, Abortion—A National Health Problem.

Clinics will be held at Tulsa hospitals Tuesday and Wednesday mornings. The president's reception, honoring Dr. Samuel A. McKeel, Ada, the incoming president, will be Tuesday evening. The Oklahoma Pediatric Society will meet Monday, May 10, with Dr. Ethel C. Dunham of the Children's Bureau, Washington, D. C., and Dr. Speed as guest speakers.

PENNSYLVANIA

Westmoreland County Clinic.—The Westmoreland County Medical Society held its fifteenth annual clinic at the Westmoreland Hospital, Chambersburg, April 22. Drs. Ambrose L. Lockwood, Toronto, Ont., and Hobart A. Reimann, Philadelphia, conducted clinics in the afternoon. At the morning session the following speakers were heard:

Dr. Robert L. Anderson, Pittsburgh, The Urologic Tract in Children.
Dr. Frederick M. Jacob, Pittsburgh, Recent Developments, Diagnosis and Treatment of Various Skin Conditions.
Dr. Joseph P. Replegle, Johnstown, A Common Undiagnosed Injury of the Shoulder Girdle.
Dr. John B. McMurray, Washington, Allergic Manifestations in the Upper Respiratory Tract.
Dr. Ralph P. Beatty, Uniontown, Urologic Disease with Gastro-Intestinal Manifestation.
Dr. Gervase F. Nealon, Latrobe, Injection Treatment of Hemorrhoids.
Dr. Maxwell Lick, Erie, president of the Medical Society of the State of Pennsylvania, was the speaker at a banquet in the evening at the Greensburg Country Club.

Philadelphia

Dr. Riesman Honored.—Dr. David Riesman was guest of honor at a dinner on his seventieth birthday, March 25, at the Bellevue-Stratford. Dr. Russell S. Boles was toastmaster and the speakers included Josiah Penniman, LL.D., provost of the University of Pennsylvania; Drs. William Gerry Morgan, Washington, D. C.; Henry A. Christian, Boston; Lewis A. Conner, New York; Alfred Stengel, and Wilmer Krusen. Dr. Stanley E. Harris announced that friends of Dr. Riesman had made possible the publication of a volume of his selected writings to celebrate his birthday. Dr. Thomas Fitz-Hugh Jr. presented to Dr. Riesman an engraved plate bearing the names of his former and present assistants. About 250 attended the dinner. Dr. Riesman is emeritus professor of clinical medicine and professor of the history of medicine at the University of Pennsylvania School of Medicine and professor of clinical medicine in the Graduate School of Medicine.

Pittsburgh

Society News.—The Pittsburgh Slit Lamp Society has changed its name to the Ophthalmological Society of the University of Pittsburgh.—Dr. John A. Toomey, Cleveland, addressed the Pittsburgh Pediatric Society, April 15, on "Differential Diagnosis Between Epidemic Meningitis and Other Forms of Meningeal Irritations."

Personal.—Dr. John E. Gorrell, superintendent of the Falk Clinic of the University of Pittsburgh since 1934, has resigned to become medical director of Blodgett Memorial Hospital, Grand Rapids, Mich. Before going to Pittsburgh, Dr. Gorrell was assistant to the superintendent of the University of Chicago Clinics. He graduated from Northwestern University Medical School, Chicago, in 1930.

RHODE ISLAND

Public Lectures.—During March the following lectures open to the public were presented under the auspices of the Rhode Island Medical Society at the Medical Library Building, Providence:

March 7, Drs. Herman C. Pitts and James A. McCann, Cancer—Facts and Fancies.
March 14, Drs. Charles S. Christie, West Warwick, and Daniel V. Troppoli, Headache—Medical and Surgical Aspects.
March 21, Drs. Charles F. Gormly, How to Grow Old Gracefully, and Henry L. C. Weyler, Why Poison Yourself—The Nostrum Evil.
March 28, Drs. Alfred L. Potter and David R. Brodsky, Modern Trends in Obstetrics.

SOUTH CAROLINA

State Medical Election.—Dr. James R. DesPortes, Fort Mill, was chosen president-elect of the South Carolina Medical Association at the annual meeting in Columbia, April 13-15. Dr. Julius H. Taylor, Columbia, was installed as president and Dr. Leonidas M. Stokes, Waterboro, was elected vice president. Dr. Edgar A. Hines, Seneca, continues as secretary. Next year's meeting will be at Myrtle Beach.

UTAH

Society News.—Drs. Ralph C. Pendleton and Reed Harrow, Salt Lake City, addressed the Cache Valley Medical Society in Logan recently on "Intestinal Obstruction" and "Subarachnoid Hemorrhage" respectively.—Dr. Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, addressed the Salt Lake County Medical Society recently on medical economics, and Dr. Arthur E. Smith, Los Angeles, on "Reconstructive Plastic and Oral Surgery."—Dr. Lyman L. Daines, Salt Lake City, addressed

the Utah County Medical Society, Provo, March 10, on "Acid-Fast Bacteria."—Dr. Leland R. Cowan, Salt Lake City, was the guest speaker at the March meeting of the Weber County Medical Society, on roentgen therapy.

WASHINGTON

Personal.—Dr. Alfred E. Eyres, recently on the staff of the health department of Seattle, has been appointed health officer of Walla Walla and Walla Walla County.—Dr. Harry C. Watkins, Hoquiam, has been appointed health officer of Grays Harbor County.—Dr. Mary E. K. Turner has been appointed campus physician at Washington State College, Pullman.

GENERAL

Syracuse Alumni Meeting.—Alumni of Syracuse University School of Medicine, Syracuse, N. Y., will meet for their annual dinner Wednesday June 9 in Atlantic City, N. J., during the annual session of the American Medical Association. Dr. J. G. Fred Hiss, 505 State Tower Building, Syracuse, is arranging the dinner.

Memorial to Dr. Bigelow.—Plans are under way to establish a memorial to the late Dr. George H. Bigelow, health commissioner of Boston and director of the Massachusetts General Hospital, Boston. A committee has been appointed composed of Dr. Henry D. Chadwick, chairman; Dr. Clarence L. Scamman, Dr. Charles F. Wilinsky, vice chairmen, and Frank Kiernan, secretary. Tentative plans have been made for a George H. Bigelow Memorial Lecture which would be presented annually. Funds will soon be solicited and definite steps taken to present the lecture.

Meeting on Industrial Medicine.—The annual meeting of the Central States Society of Industrial Medicine and Surgery will be held in Peoria, Ill., May 18. The speakers will include:

- Dr. Darwin Kirby, Champaign, Ill., Treatment of Wounds.
- Dr. Harry A. Olin, Chicago, Injuries to the Intervertebral Disk—Roentgen Study.
- Dr. John B. Moore, Benton, Ill., The Economic Aspect of Abdominal Drainage.
- Dr. Philip H. Kreuscher, Chicago, Medical Problems of the Industrial Commission.

American Psychiatric Association.—The ninety-third annual meeting of the American Psychiatric Association will be held in Pittsburgh, May 10-14, at the William Penn Hotel. There will be special section meetings devoted to convulsive disorders, forensic psychiatry, child psychiatry, pathology of the brain, mental deficiency and the hypoglycemic treatment. There will also be joint sessions with the American Psychopathological Association and the American Psychoanalytic Association. Dr. Charles Macfie Campbell, Boston, is president of the association.

Changes in Status in Licensure.—The State Board of Medical Examiners of Florida announces that the licenses of the following have been revoked for narcotic violations:

Drs. Raymond O. Cheney, Daytona Beach; James F. Curry, Dunnellon, and Charles C. Gollinger, Daytona Beach.

The Montana Board of Medical Examiners recently took the following action:

Dr. James E. K. Free, Joplin, license revoked for conviction of the unlawful sale of drugs.

At a meeting of the State Medical Board of Ohio in Columbus January 5, the following actions were taken:

License of Dr. Charles R. Buck, Cincinnati, suspended until July 1, 1938, for violation of the Harrison Narcotic Act.

License of Dr. Robert I. McPhail, Arcadia, suspended for one year for violation of the narcotic act.

License of Dr. Ralph B. Brown, Belle Center, suspended until October 1, for violation of the narcotic act.

The West Virginia Public Health Council at a meeting March 2 took the following action:

License of Dr. Clyde H. Scott, Huntington, revoked for conviction of a felony.

License of Dr. Elias Benjamin Thompson, Williamson, for conviction of narcotic violation.

CANADA

Personal.—Dr. Jonathan C. Meakins, Montreal, has gone to Australia, where he will deliver a series of lectures at the invitation of the graduate committee in medicine of the University of Sydney, New South Wales.—Dr. Ian MacLaren Thompson, professor of anatomy, University of California Medical School, Berkeley, has been appointed professor of anatomy in the University of Manitoba Faculty of Medicine, Winnipeg.

Rural Health Conservation Contest.—The Canadian Public Health Association has arranged to conduct a public health conservation contest for rural areas with full time

health service, in cooperation with the American Public Health Association, which has carried on such contests in the United States for several years. The project in both countries is financed by a grant from the W. K. Kellogg Foundation. A fact-finding schedule taken principally from the appraisal form published by the American association will be used and field service will be furnished from the full time staff of the American association. The first contest will be held in the spring of 1938. Dr. Albert Grant Fleming, Montreal, is chairman of the committee and Dr. John T. Phair, Toronto, secretary.

FOREIGN

Medical Meetings.—The fifth International Hospital Congress will be held in Paris July 5-12. Among the speakers will be Dr. Malcolm T. MacEachern, Chicago; Mr. Homer Wickenden, president of the United Hospital Fund, New York, and Dr. Clarence M. Hincks, Toronto and New York, director of the National Committee for Mental Hygiene and the Canadian Committee for Mental Hygiene.—The "International Medical Days of Paris" will be held June 26-30. The subject to be discussed is the influence of hormones in biology, clinical medicine and therapeutics. The secretary general is Dr. Pierre Godlewski, 18 rue de Verneuil, Paris.—The annual "Journées médicales" will be held in Brussels June 19-23, under the presidency of Prof. Albert P. Dustin, rector of the University of Brussels. Dr. Georges Duhamel, Paris, will lecture at the opening session. Information may be obtained from the secretary general, Dr. René Beckers, 141 rue Belliard, Brussels.—The seventh English-Speaking Conference on Maternity and Child Welfare will be held in the Great Hall, British Medical Association, Tavistock Square, London, W. C. 1, June 1-3.—Paris laryngologists are organizing a congress of laryngologists to be held July 13 in conjunction with an "International Congress of Singing" at the Paris Exposition. Dr. L. Labarraque, 78 rue de Miromesnil, is in charge of arrangements.

Government Services

Hygienist Named to Department of Agriculture

Dr. Harry S. Bernton, professor of hygiene, Georgetown University School of Medicine, Washington, D. C., has been appointed clinical specialist in allergy in the bureau of chemistry and soils of the U. S. Department of Agriculture. Dr. Bernton will participate in a research project concerning the chemical nature of allergens, planned by the department, according to the *Medical Annals of the District of Columbia*.

Statistical Activities in Children's Bureau Reorganized

Mr. Robert J. Myers, Chicago, in the past four years director of research and chief statistician of the Illinois Emergency Employment Commission and of the Illinois Works Progress Administration, has been made director of the division of statistical research of the Children's Bureau of the Department of Labor. This division is a consolidation of three former statistical units in the bureau.

Opening for Associate Physicist (Electro-Encephalography)

The U. S. Civil Service Commission announces an open competitive examination to fill the position of associate physicist (electro-encephalography) in the U. S. Public Health Service. The salary for the successful applicant will be \$3,200 a year, which is subject to 3.5 per cent deduction toward a retirement annuity, and the duties will be to design, construct, repair and carry on research work on apparatus, to measure the electric potential of the brain, and to perform research work in the field of bio-electrical phenomena. Applications must be on file with the civil service commission at Washington, D. C., not later than May 20 for those coming from Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming and May 17 for applications coming from any other state. Application forms may be obtained from the secretary, Board of U. S. Civil Service Examiners, at any first class post office, from the civil service commission, Washington, D. C., or from the civil service district office at any of the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco and Honolulu.

Birth Control

The problem of local authorities and birth control has been under discussion for some time. Many have wished to provide facilities by which poor mothers could obtain advice but were unable to do so until 1931, when the Ministry of Health issued a memorandum pointing out that three courses were open to them: 1. Advice could be given to married women attending child and maternity welfare centers when further pregnancies would be detrimental to health. 2. Birth control clinics for this limited purpose could be established under the powers existing for the care of expectant and nursing mothers. 3. Under the public health acts, gynecologic clinics could be established for women in need of advice, and contraceptive advice could be given there to married women attending in whom pregnancy would be detrimental to health. However, these provisions were not considered sufficient by some, and in February the minister of health received a deputation organized by the National Birth Control Association, which pointed out the inadequacy of the present provisions and the limited use made of their powers by local authorities. The deputation predicted that increased provision would lead to a reduction not only in maternal morbidity and mortality but also in criminal abortion. They urged the minister to encourage the local authorities to establish gynecologic clinics in which birth control might take its proper place as part of the general care of women. In reply the minister pointed out the limitations imposed by parliament both on him and on the local authorities, stating that any alteration of policy would have to receive parliamentary approval. He contemplated an extension of postpartum clinics, where facilities would be available for the medical examination and treatment of women who had recently been confined. Birth control advice could be given there to any woman in whom pregnancy would be detrimental to health, but he considered that it should be given in a separate session. The establishment of postpartum clinics would doubtless reveal the need in many areas for gynecologic clinics, where this advice also could be given.

Physical Training Bill

As shown in previous letters, the closely connected subjects of diet and physical training of the public are now in the forefront of politics, and another one—the imminent fall of population due to the declining birth rate—is beginning to attract public attention. In the House of Commons Mr. Oliver Stanley, president of the Board of Education, moved the second reading of the physical training and recreation bill, which establishes a national advisory council, which, in conjunction with local bodies, will provide physical training for the people. The chairman of the council will be Sir Henry Pelham, permanent secretary to the Board of Education. A national college is to be set up for the training of instructors. Mr. Stanley said that in the last few years more publicity had been given to physical training in Germany and Italy, which might or might not be militaristic, but it was the democratic states Sweden and Czechoslovakia that first set an example to Europe in this training. He thought we should draw valuable lessons from their systems, which had no element of compulsion, but at the same time we would not ignore the developments that had taken place in the last twenty or thirty years in our own country. We had not any less enthusiasm for physical exercises, but, while they concentrated on the training and development of the body of the individual, we had concentrated on games and the team spirit. This had the danger that in a

highly urbanized state the participant tended to degenerate into the spectator. We did not want to substitute physical training for games but to supplement them with it. The "keep fit" slogan was one of the best ever invented. What was not so widely known was the remedial effect of physical training on some of those minor, and indeed some of the major, ills to which a highly civilized and industrialized community was liable. The habits of our civilization did result in certain physical defects. The machinery necessary to ensure that the school child should come to physical training with a well nourished body was now provided. The scheme was directed not only to physical training but also to recreation. The modern industrial trend was to shorten working hours. The masses of the people had greater leisure than ever at any time in our history. This leisure required something more than football matches and cinemas. The government scheme would not confine assistance to activities of the body but would include activities of the mind. Bertrand Russell had said "To be able to fill leisure intelligently is the last product of civilization."

Varicocele in the Female

At the North of England Obstetrical and Gynecological Society Prof. Fletcher Shaw reported six cases of varicocele in the female, a condition of which the textbooks do not give a satisfactory account. His attention was first directed to it in 1921 by the late W. E. Fothergill, and at first he was skeptical about the essential nature of a complaint that could be recognized only when the patient was in the upright position. But in 1923 he had three cases in one month. An unmarried woman, aged 26, was curetted by him in 1922 and underwent laparotomy in 1923 for suspected chronic salpingitis. But he found a mass of veins in the left broad ligament, which he ligatured and excised. A year later severe right-sided abdominal pain necessitated a second laparotomy, when the right ovary was found to be cystic and there was a mass of veins in the right broad ligament. The right tube and ovary were removed with this mass. The patient recovered and had a family. In another case a primipara, aged 31, had aching pains in both iliac regions and a mass of veins was removed from the left side. A year later the symptoms recurred and a similar mass was removed from the right broad ligament and panhysterectomy was performed.

Some writers have stated that retroflexion is a cause of this condition, but Shaw has found this in only one case. In each of his cases the mass was large enough to suggest a pelvic tumor. In five cases the pain was left sided. In the first three cases he excised the veins without curing the patient, but in the others a more drastic procedure proved successful. The etiology of the condition was obscure. He thought it was more common than is generally supposed and that the usual treatment was unsatisfactory.

Instruction in Air Raid Precautions

The government scheme of appointing medical instructors for service in the Air Raids Precautions Department was begun in September 1936 with ten physicians who had been trained in the Civilian Anti-Gas School. It soon became apparent that for the instruction of the medical, dental, veterinary and nursing professions this number was inadequate, and therefore six further trained instructors were appointed in December. By the end of January 3,300 persons had been instructed: 1,600 physicians, 1,300 nurses and 400 medical students. The majority of the physicians were reached through the British Medical Association, twenty of whose branches have already received a complete course of instruction and another thirty are at present receiving one. In some cases, when desired by the trainees, an examination was held and all but a small percentage reached a qualifying standard. The demand for instruction is now so great that there is difficulty in complying with it and programs are booked many months ahead.

Rockefeller Traveling Fellowships

The Medical Research Council has been entrusted by the Rockefeller Foundation, New York, with \$15,000 annually for three years in the first instance, for the award of traveling fellowship in medicine to candidates in the United Kingdom. This benefaction renews an arrangement that was highly successful during an earlier period but which had latterly been interrupted during a revision of the general policy of the foundation. These fellowships are intended for graduates who have had some training in research in clinical medicine or surgery or other branch of medical science and are likely to benefit by a period of work at a chosen center in the United States or elsewhere before taking up a position for higher teaching or research in this country. An analysis made at the end of the previous ten year period, of the positions occupied by the seventy men and women who had completed their tenure of the Rockefeller fellowships awarded by the council, show that twelve are professors in universities, that the others occupy whole time positions for teaching and research, and that sixteen hold part time positions of the same kind.

Universal Decline in Number of Marriages

In the March 10 issue of the *Presse médicale* appeared an article by Dr. Philippe Dally stating that in 1935 the number of marriages had increased in fifteen countries, remained unchanged in three and declined in twelve. In Germany there was a 15 per cent increase in 1934 but a decrease of 12 per cent in 1935, being 9.7 per thousand in the latter year as compared to 11.1 per thousand in 1934. Governmental measures, such as loans and gifts to newlyweds, have not been followed by an increase in the number of marriages. The same was true of Italy's encouragement measures, the increases registered in 1933 and 1934 being practically nullified by the decrease of 11 per cent in 1935. The proportion of marriages in Italy has fallen from 7.4 to 6.6 per thousand, a figure lower than ever before noted. The country in which the drop in 1935 has been most marked is Bulgaria (7.8 instead of 9.3 per thousand). In France, although the drop was not so striking, the number being 6.8 in 1935 instead of 7.1 per thousand in 1934, this is not surprising, as the number of marriages has been low for a number of years. In fifteen countries there has been an increase. Australia and New Zealand head the list, with northern Ireland next. The proportion remains unchanged in the United States, being at present 10.4 per thousand.

Antibotulism Anatoxin

Drs. Weinberg and Goy of the Pasteur Institute have succeeded in preparing an anatoxin against botulism. They have shown that it is possible to vaccinate animals with this anatoxin and even to prepare an *antibotulinus serum* against the two most toxic types (A and B) of the bacillus. The serum is more active toward the A than toward the B type. They have followed the same technic as in their preparation of the polyvalent antigangrene serum.

In 194 cases of botulism, Welikanov, a Russian bacteriologist, used the A and B antibotulism serum in 119. Only twenty-four (20 per cent) of the patients died. The serum was not given to the remaining seventy-five patients, and seventy (93 per cent) of these untreated persons died.

In an article in the February 1 issue of the *Siècle médical* by Kazcef, in which the subject of botulism is reviewed, the author concludes by stating that, as the result of this use of antibotulism serum the treatment of this type of infection appears to be solved.

Relation of Alcohol to Cancer of Esophagus

At the February 23 meeting of the Académie de médecine a paper on the relation of alcohol to cancer of the esophagus was presented by Piquet and Tison. Out of 110 patients, 102 (93 per cent) were heavy drinkers. Of the 110 cancers of the esophagus, 101 were found in men. In alcoholic addicts, eighty-two were in the upper and twenty in the lower part of the esophagus. In abstainers, four were in the upper and four in the lower portions. The fact that alcohol remains a longer time in the upper part of the esophagus led the authors to ascribe an etiologic relation of the alcohol to the larger number of high-lying cancers. They believe that alcoholic drinks cause a chronic irritation followed by metaplasia of the epithelial lining and hence they are a cancerigenic agent of much importance.

French Gynecologic and Obstetric Congress

The next French Gynecologic and Obstetric Congress will be held in Paris September 30-October 2. The subjects of the collective reviews for this year's meeting will be: 1. Treatment of urinary incontinence in women: Drs. Muret and Rapin of Lausanne, Switzerland. 2. Treatment of vesicovaginal fistulas: Prof. Paul André of Nancy. 3. Pathogenesis and treatment of uteroplacental apoplexy: (a) Pathogenesis: Prof. Alexandre Couvelaire of Paris. (b) Treatment: Dr. Auguste Weymeersch of Brussels. 4. Treatment of pruritus vulvae: (a) Medical treatment: Dr. Vayssière of Marseilles. (b) Surgical treatment: Dr. Cotte of Lyons.

Meeting of French Ophthalmologic Society

The fiftieth annual meeting of the French Ophthalmologic Society will be held June 28-30 in Paris. The subject of this year's collective review (Rapport) will be Optochiasmatic Arachnoiditis, read by Dr. Bollack of Paris. For all information, address Dr. R. Onfray, 6 Avenue La Motte-Picquet, Paris (7).

News of the Universities

Recently additional regulations with respect to the granting of the title of doctor were instituted (*THE JOURNAL*, Nov. 16, 1935, p. 1619). Several further noteworthy prerequisites have been decreed. A doctoral candidate must now have studied for at least two semesters at the university bestowing the degree. All dissertations must henceforth be written in German and the diplomas, which previously had been drawn up in Latin, in accordance with ancient tradition, shall hereafter be written in the German language. The revocation of a doctoral degree has now been extended to apply to persons who have renounced or been deprived of their German citizenship. An exception to this rule is that the mere fact of Jewish racial origin does not justify revocation of the title.

The rumor that the number of German universities is to be reduced continues rife in academic circles, despite repeated official denials. One hears it said on the part of the docents that it would be better to strengthen the smaller universities at the expense of the larger, since in the latter the personal feeling between teacher and student is easily lost.

It has already been reported (*THE JOURNAL*, June 15, 1935) how the maximal number of students in certain universities has been fixed by law. This measure was destined to divert the great numbers of students crowding the big city universities to the smaller and less well attended schools. The results have been diverse. In the winter semester of 1935-1936, the most recent semester for which complete figures are available, the aggregate enrolment of all twenty-three German universities was 60,048; namely, less than half the enrolment during the summer semester of 1932. Berlin continues to show the largest

enrolment of any German university. There were 10,000 students registered there in the summer of 1933. With the general retrogression of the academic world, this figure had sunk to 7,278 in the summer of 1934. The maximal contingent for Berlin was then fixed at 6,600, but this limit has been overstepped, for 8,220 were enrolled in the winter semester of 1935-1936. At Munich, second only to Berlin in point of attendance, the number of students declined from 8,000 to 7,000 and the fixed contingent of 5,200 students was not exceeded. The falling off in attendance has been even more abrupt at Leipzig; 6,400 students were in residence there in 1933, whereas only half as many are registered today. The present enrolment corresponds roughly to the stipulated limit. In most of the universities attendance has generally been kept within the bounds of the prescribed contingents, although these have occasionally been exceeded, as at Hamburg and Cologne. The movement to allocate more students to the medium-sized university towns has to a certain extent been successful, especially at Freiburg and Heidelberg, two well liked schools which reported relatively large registrations for the winter semester of 1935-1936: Freiburg more than 3,000 students, Heidelberg around 2,600.

The average proportion of women in the university student population is 13 per cent. At Hamburg, however, 33 per cent of the students were women; at Berlin, 17 per cent. Several of the other universities are less favored by the woman student.

Berlin University has published as one of a series of advisory pamphlets for students some interesting data on the academic expenses of the individual student. On entering a university the student is assessed a matriculation fee of about 30 marks. A so-called general fee (for sickness and accident insurance, use of the university libraries and so on) also comes to about 30 marks. Then there is a "study fee" of 80 marks and in addition there are the "lecture fees" for admittance to lectures and to other exercises. These are computed at the rate of 2.5 marks per weekly semester-hour; thus if a lecture course meets four times each week the charge for the entire semester will be 10 marks. Besides, students in the natural sciences and in medicine are required to pay special fees for use of the laboratories and so on, which amount to about 35 marks. Although the sum total of the student's academic expenses will depend largely on the number of lectures attended, some rough estimates have been hazarded. According to these a medical student in his first semester will pay the university from 210 to 230 marks and in subsequent semesters from 230 to 250 marks. A medical student's books will in addition cost him from 50 to 70 marks and he will occasionally have to purchase instruments as well.

To the foregoing must be added the examination fees. German candidates for the doctorate in medicine pay 200 marks, foreigners 300 marks. The examination taken by the foreign student is known as the "Medizinische Rigorosum." The costs of printing a dissertation average from 200 to 400 marks. Further expenses are incurred by those who take the state examination in medicine. Altogether the prospective physician must figure on an outlay of from 3,500 to 4,000 marks for academic expenses alone.

The foregoing data may be supplemented by estimates on the minimal living expenses of students, which were recently set forth in a widely circulated booklet entitled "The University Guide." Unless the school is located in the student's home town he must figure on residing at the university during the two semesters of each academic year; namely, seven months out of the year (three summer months, four winter months). The following minimal estimates of a student's monthly living expenses are of particular interest: lodging and breakfasts, 25 marks; dinners and suppers at the students' commons, 30 marks; dinners and suppers on Sunday, when the commons

is closed, an additional 10 marks; pocket money for incidentals, 15 marks, a niggardly estimate; books (other than textbooks), paper and so on, 12 marks. The minimal monthly budget for living expenses thus comes to 92 marks. This figure, however, represents an uncommonly low estimate of expenses and no student could "get by" on such a small allowance without suffering privations. Nevertheless there are many students who never spend as much as this estimated minimum. On the basis of 92 marks per month, living expenses will amount in five or six academic (seven month) years of residence at the university to between 3,000 and 4,000 marks. Thus the grand total of estimated expenditures incident to a university education will be between 7,000 and 8,000 marks. The extent to which organized financial aid to students is helping to ameliorate the situation was also recently discussed. Nearly every tenth student is a recipient of these aids in some form or another.

Thoracic Tumors

According to recent German statistics, pulmonary carcinoma is the only type of cancer that has exhibited a universally sharp increase. Professor Cramer, who recently discussed this problem in the Berlin Medical Society, believes that bronchial carcinoma is not based on any single etiologic factor but on a complex of factors. Metaplasias of tissue on the basis of an inflammation may, together with factors such as tobacco, heat and other injurious agents, lead to the formation of cancer. In Japan, for example, five per thousand of the generator gas workers develop bronchial carcinoma. These workers not only are forced to inhale dust but are exposed to the noxious influences of poisonous gases and heat as well. Locomotive engineers, on the other hand, although accustomed to a similar inhalation of dust, are not subject to the disease. In elderly patients who present coughs, dyspnea, chest pains, paralysis of the recurrent laryngeal nerve or of the phrenic nerve, this diagnosis should be thought of. For differential diagnosis, lateral visualization, shutter exposure and bronchography are most important; slight unilateral impairment of respiratory function may be detected by means of the kymogram at a time when as yet no large tumor shadows are present. Bronchial carcinoma usually metastasizes quickly. Animal experimentation shows that in patients with low immunity fatal pneumonia may follow a roentgen irradiation if powerful doses are employed. Early diagnosis and a preliminary amelioration of the toxic condition are therefore prerequisites of a successful therapy.

ITALY

(From Our Regular Correspondent)

March 15, 1937.

Treatment of Chronic Malaria

Prof. Maurizio Ascoli, head of the medical clinic of the University of Palermo, in a recent lecture to the army physicians, reviewed the principles on which his method for the treatment of chronic malaria is based. He noticed that many patients who suffer from chronic malaria recover from the disease by living in high altitudes. This fact is due, he believes, to the physiologic contracture of the spleen caused by the high altitude. He reproduced the contracture of the spleen in malarial patients by intravenous injections of progressive doses of from 0.01 to 0.2 or 0.1 mg. of epinephrine. Examination of the patient shortly after the injection shows progressive contracture of the spleen. When contracture stops the organ expands slowly again, but it never returns to its size previous to the injection. The process of contraction and reexpansion of the spleen is repeated by every new injection and at last the spleen returns steadily to its normal size. During each contraction the spleen delivers the malarial parasites to the blood. At the end of the treatment splenomegaly has entirely disappeared and the blood dyscrasia and general condition of

the patient improve. Intravenous epinephrine injections, with or without small doses of quinine, also give satisfactory results in acute malaria. Up to the present no recurrences have been observed in the several patients who received the epinephrine treatment.

Morgagni's Endocraniosis

Prof. Nicola Pende, head of the Istituto di patologia medica of Rome University, in a recent lecture to the Accademia Medica of Rome spoke on Morgagni's intracranial hyperostosis. Patients with this disease suffer sometimes from intractable frontal headaches and apathy, asthenia and psychic depression. In other cases there are sexual disturbances complicated either by obesity or by emaciation. Some patients suffer from diabetes insipidus, disorders of sleep, psychic changes, irritability, neurasthenia and in some instances dementia. Other patients show progressive blindness or deafness, loss of the sense of smell, epileptiform and involuntary sudden muscular contracture. Symptoms belonging to the different groups may appear sometimes in association. According to the speaker, the cause is the presence of a special lesion on the internal surface of the cranial bones, which is more frequent at the frontal and basal regions than on the other internal regions of the cranium. The lesion was described for the first time by Morgagni. It consists in new formation of bone tissues, which protrude as patches or bands at the internal aspects of the cranial bones and cause irritation or compression of the brain, with consequent circulatory disturbances at the prefrontal and frontal lobes and at the base of the brain. From the literature it seems that the lesions are located at the internal frontal region. They have been found on the internal aspects at the base of the cranium. Bertolotti found through x-ray studies that infection of the cranial or facial sinuses may spread intracranially to the internal aspects of certain cranial bones and to the dura mater, with consequent thickening of the involved bones. The process may originate also in nutritional disturbances of the bones or of the dura mater. In all cases hypophyseal and neurohypophyseal disorders may coexist.

Atabrine and Malaria

The Supreme Council of Public Health accepted atabrine as a subsidiary product of quinine for the treatment of malaria in municipal centers. The minister of the interior, in giving instructions as to the use of atabrine to the authorities of provinces and municipal towns, said that atabrine is prepared in 0.1 Gm. tablets and will be prepared and sold through supply centers organized by the government. Atabrine is an acridine synthetic derivative having a malarial parasiticide action which, in the course of the malarial attack, has the same action as quinine. The daily therapeutic dose for adults is 0.3 Gm. divided into three doses of 0.1 Gm. each for at least seven consecutive days. The daily preventive dose is 0.05 Gm. In certain cases the appearance of a yellow pigmentation of the skin follows the administration of atabrine. This is a reaction of the skin to the drug. It should not be mistaken for jaundice, because the drug has no action on the liver or on the blood. At the present time atabrine will be given for malaria only to adults in hospitals, clinics and centers for ambulant patients.

Surgical Collapse Therapy

Professor Omodei-Zorini of the University of Rome, in a recent lecture before the Federazione per la lotta contro la tubercolosi, reported results of simple apicolysis in pulmonary tuberculosis. Forty-four operations were performed from one to four years ago. The best results were those obtained in recent apical and subapical cavitations and in chronic micro-nodular tuberculosis with or without relapsing hemoptysis of the apex. Less satisfactory results were obtained in dense

fibrous tuberculosis of the apex, with or without cavitation, and in lobitis with retraction, and cavitation. Large solitary cavities of the apex and apical ulceration with a tendency to propagate itself apicocaudally were not modified by the operation. On the whole, satisfactory results were obtained in 47.7 per cent of the cases, incomplete results in 20 per cent and no effect on the condition in 32.3 per cent. Good results were also reported from paraffin filling in seventeen cases. In twelve cases in the group the operation was primary and autonomous. Permanent recovery was obtained in two cases. According to the speaker, paraffin filling is a delicate procedure, which may be followed by complications. Nevertheless, if the operation is performed by a good technic and according to precise indications, satisfactory results may be obtained. The indications for performing posterior apical thoracoplasty were discussed. It is, he stated, the operation of choice in the treatment of rigid cavities with adhesions at the apex of the lung. At the suggestion of the speaker, Dr. Ascoli reported results obtained in a group of twenty patients from posterior apical thoracoplasty. The operation was made a few months or a year ago. In eleven cases the cavities rapidly regressed and the sputum showed no more tubercle bacilli. In seven cases the outcome was not as yet complete. Two patients died a month after the operation. One of the patients died from contralateral exudative pleuritis and the other one from toxemia and cardiorespiratory insufficiency.

Graduate Studies

The national board of education met recently under the chairmanship of the ministry of the department of public education. The advisability of reducing the number of schools for specialization in medicine and graduate study was discussed. There are now 279 schools of this nature in Italy, 144 of which are connected with faculties of medicine and surgery. The minister said that it is advisable to close the schools at which the recent attendance has not been sufficient. The minister's motion met with the approval of the board. It was resolved that from now on the curriculum, duration of studies and character of examinations of the schools for specializing and those for postgraduate studies would have to conform to the regulations established by the board. The relative values given to certificates for graduate studies and to diplomas delivered from schools of specialization will also be determined. The regulations were placed in the hands of an executive committee.

Annual Book of Hospitals of the World

On the occasion of the exhibit of the replicas of the hospitals of several nations, which will be shown in Milan in the near future, a resolution was accepted by the members of the international association of hospitals. It concerns publication of an annual book written in five languages which aims to give actual information on the existence, organization, functions and development of hospitals all over the world. The expenses for publication of the book and related expenditures will be met by the international association of hospitals.

Marriages

HERMANN L. WITTE, Trenton, N. J., to Miss Erika Loes of Freiburg, Germany, in New York, February 6.

JAMES A. SELIGMAN, Philadelphia, to Miss Eleanor Bains Brown of Bala, Pa., April 9.

WALTER RAYMOND WASCHICK, Rossville, Ill., to Miss Mellic Gant at Sheldon, January 30.

WILLIAM DUNSFORD LYON, Akron, Ohio, to Miss Pearl Beulah Lyon, February 1.

GERALD THEODORE SCHWARZ, Akron, Ohio, to Miss Iva Patton, January 28.

Deaths

George Walker, Baltimore; University of Maryland School of Medicine, Baltimore, 1888; member of the Medical and Chirurgial Faculty of Maryland; fellow of the American College of Surgeons; was an assistant in the outpatient surgical department, 1898-1900, chief of clinic, 1900-1902, instructor in surgery, 1902-1905, and later associate in surgery, Johns Hopkins University; during the World War went to France with the Johns Hopkins Unit, four months later was detached and assigned to ocean ports for work in prevention of venereal disease, and in December 1918 was appointed urologist in chief to the American Army in France; in 1922 was awarded the Distinguished Service Medal; in 1921 was awarded the honorary doctor of laws by the University of South Carolina; in 1934 was appointed chairman of the medical advisory board of the Baltimore City Hospitals; aged 67; visiting surgeon to the Church Home and Infirmary and the Union Memorial Hospital, where he died, March 31.

Milton Jay Greenman, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1892; director of the Wistar Institute of Anatomy and Biology since 1905 and assistant director, 1893-1905; lecturer on physiology, Biological School of the University of Pennsylvania, 1892-1893, and instructor in biology, 1887-1892; member of the American Association of Anatomists, American Society of Naturalists, American Philosophical Society and the Philadelphia College of Physicians, and of other scientific organizations; served as trustee to the Marine Biological Laboratory, Woods Hole, Mass., Vineland (N. J.) Training School, Laboratory of Biological Survey of the Mount Desert Region, Bar Harbor, Maine, and Yale Laboratories of Primate Biology; was awarded the honorary degree of doctor of science by the University of Pittsburgh in 1912 and by the University of Pennsylvania in 1919; aged 70; died, April 7, in the University of Pennsylvania Hospital.

James Leslie Busby ♂ Pasadena, Calif.; Starling-Ohio Medical College, Columbus, 1913; associate professor of medicine at the College of Medical Evangelists; fellow of the American College of Physicians; served during the World War; formerly assistant chief medical adviser in the Bureau of War Risk Insurance, and chief of the section of medicine and surgery, hospital division of the United States Public Health Service; served in various sections at the Mayo Clinic, Rochester, Minn.; on the staff of the Los Angeles County Hospital, Pasadena and St. Luke's hospitals; aged 46; died, February 18, of carcinoma of the bronchus.

Otis Sumter Warr ♂ Memphis, Tenn.; University of Nashville (Tenn.) Medical Department, 1907; professor of medicine at the University of Tennessee College of Medicine; fellow of the American College of Physicians; president of the Memphis and Shelby County Medical Society; served as a member of the medical advisory board during the World War; on the staffs of the Gantly-Ramsay Hospital, Memphis General Hospital and Methodist Hospital; aged 55; died, March 22, in St. Mary's Hospital, Knoxville, of lobar pneumonia.

Alvin J. Lorie ♂ Kansas City, Mo.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1911; county coroner; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; visiting otolaryngologist to St. Joseph, Research, Kansas City General and Menorah hospitals; aged 50; died suddenly, March 8, in Miami Beach, Fla.

Mark D. Hollis, Savannah, Ga.; Baltimore Medical College, 1898; acting assistant surgeon, U. S. Public Health Service, at the U. S. Immigration Station from November 1913 to August 1936 and was retired for disability in September 1936; served at many stations of the service and was medical officer in charge of the U. S. Quarantine Station, Savannah, from August 1930 to 1936; aged 62; died, February 15, in Buena Vista, of coronary occlusion.

William A. Durringer, Fort Worth, Texas; Tulane University of Louisiana Medical Department, New Orleans, 1885; member of the State Medical Association of Texas; fellow of the American College of Surgeons; member of the staff of St. Joseph's Hospital; consulting surgeon to the Chicago, Rock Island and Gulf Railroad; division surgeon to the Southern Pacific Lines; aged 75; died, February 18, of myocarditis and encephalitis.

Frank Harrison, Dallas, Texas; Southern Methodist University Medical Department, Dallas, 1915; member of the State Medical Association of Texas; served during the World War; at one time connected with the U. S. Public Health Service; formerly instructor in clinical neuropsychiatry at Baylor University College of Medicine; on the staff of the Baylor University Hospital; aged 50; died, February 15, of influenza and pneumonia.

Harrison Sales Forgrave ♂ St. Joseph, Mo.; Central Medical College of St. Joseph, 1897; past president of the Buchanan County Medical Society; president of the board of health; fellow of the American College of Surgeons; formerly professor of pediatrics at the Ensworth Central Medical College; aged 63; member of the staff of Missouri Methodist Hospital and St. Joseph's Hospital, where he died, February 14, of embolism.

Willis G. Gregory, Buffalo; University of Buffalo School of Medicine, 1882, and a degree in pharmacy in 1886; professor of pharmacy at the University of Buffalo School of Pharmacy since 1886 and dean of the school from 1890 to 1936; was a member of the state board of pharmacy for many years and of the U. S. Pharmacopoeial Revision Committee from 1890 to 1920; aged 79; died, March 20, of cerebral hemorrhage.

Reuben Adolphus Campbell ♂ Major, U. S. Army, retired, Dallas, Texas (licensed in North Carolina in 1897); served during the World War; entered the medical corps of the U. S. Army as a major in 1920 and retired in 1933 for disability in line of duty; aged 67; died, February 26, in the Station Hospital, Fort Sam Houston, San Antonio, of chronic lymphatic leukemia.

Marie Pelecovich, Worcester, Mass.; University of Michigan Medical School, Ann Arbor, 1932; member of the Massachusetts Medical Society; on the staffs of the Holden (Mass.) District Hospital and the Harvard Private Hospital; on the courtesy staff of the Fairlawn Hospital; aged 29; died suddenly, February 8.

Charles Eliakim Norton, Lewiston, Maine; Medical School of Maine, Portland, 1876; member of the Maine Medical Association; for many years on the staff of the Central Maine General Hospital; aged 84; died, February 19, of influenza, nephritis and pneumonia.

Thomas Wynne Watts, Portland, Ore.; Kentucky University Medical Department, Louisville, 1906; member, and was president for 1936-1937 of the Oregon State Medical Society until he resigned, March 24, because of ill health; aged 58; died, March 26.

Charles Everett Rankin, Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; aged 73; died, February 24, of chronic myocarditis and bronchiectasis.

Aurelius Thomas Siemianowski ♂ Chicago; Chicago Medical School, 1927; aged 34; on the staff of the Auburn Park Hospital, where he died, February 25, of bronchopneumonia.

Adolph Antone Maulhardt, Oxnard, Calif.; Harvard University Medical School, Boston, 1897; aged 63; died, February 15, in St. John's Hospital, of pneumonia and acute nephritis.

James Richard Lewis, Burlingame, Calif.; Bellevue Hospital Medical College, New York, 1885; aged 78; died, February 5, of chronic myocarditis and arteriosclerosis.

Horace Leland Hulett, Milton, Wis.; University of Buffalo School of Medicine, 1896; aged 65; died, February 2, of lobar pneumonia, paralysis agitans and angina pectoris.

Erasmus Edward Adams, Marshall, Ark.; University of Michigan Homeopathic Medical School, Ann Arbor, 1877; aged 84; died, February 3, of pneumonia.

Rudolf Frederick Rohlfing, Los Angeles; Northwestern University Medical School, Chicago, 1906; aged 56; died, January 14, of acute myocarditis.

William Bedford Keeton, Medina, Tenn.; Vanderbilt University School of Medicine, Nashville, 1895; aged 73; died, February 4, of chronic nephritis.

James Mitchell Armstrong, Calgary, Alta., Canada; University of Toronto (Ont.) Faculty of Medicine, 1893; aged 72; died, February 9.

John Bolinger, Springfield, Mo.; Missouri Medical College, St. Louis, 1882; aged 78; died, February 8, of carcinoma of the liver.

Joseph J. L. Finnell, Peoria, Ill.; Louisville (Ky.) Medical College, 1898; aged 68; died, February 18, of carcinoma of the bladder.

John Alfred Smither, Stockton, Calif.; Gross Medical College, Denver, 1899; aged 64; died, February 7.

Correspondence

"SURGICAL TREATMENT OF MALIGNANT HYPERTENSION"

To the Editor:—With reference to the editorial in THE JOURNAL, February 20, entitled "Surgical Treatment of Malignant Hypertension," may I call attention to the omission in this editorial of reference to the report of the first case of malignant hypertension subjected to bilateral lumbar sympathectomy. This was reported in THE JOURNAL, Sept. 26, 1925, in an article entitled "Bilateral Lumbar Sympathetic Neurectomy in the Treatment of Malignant Hypertension," by Leonard G. Rowntree and Alfred W. Adson.

LEONARD G. ROWNTREE, M.D., Philadelphia.

VINCENT'S STOMATITIS AND GRANULOCYTOPENIA

To the Editor:—That no mention of agranulocytic angina or granulocytopenia was made by Farrell and McNichols in their article on the efficacy of various medicaments in the treatment of Vincent's stomatitis (THE JOURNAL, February 20) is a surprising omission. Attention should be called to the necessity for a leukocyte and a differential count in any case of severe stomatitis, no matter what organisms are found in the mouth. Certainly the blood smear should be examined before using neoarsphenamine or strong local applications advised elsewhere. In the article referred to, three cases of noma are reported without mention of the leukocyte count, although a benzene nucleus was given therapeutically in cases 1 and 2. A patient with Vincent's stomatitis with granulocytopenia under my care received poor treatment and I feel that this point should be drawn to the attention of your readers to save others from similar error. No practitioner should feel that he has completed the investigation of a case of stomatitis because he has found Vincent's organism in a smear.

DAVID CHRISTIE, M.D., Elfros, Sask.

INJECTION METHOD IN TREATMENT OF HERNIA

To the Editor:—On page 542 of THE JOURNAL, February 13, I am quoted, but with such omission as to invert the meaning of my own plain statements. The author refers to me in these words: "He 'naturally' assumes that, if patients do not return their hernias are 'gone and forgotten.'" Reference to my original article discloses, however, that I am not as naïve as this would indicate. What I actually said was:

I cannot speak with such certainty in the matter of recurrences, for we too often lose track of our old cases. I ask my patients to return in six months and again in a year, and often they do. Too often, however, I never see them again, and since my arrangements invite their return if any weakness appears, I naturally assume that their hernias are gone and forgotten. Among the more careful patients who do return for a check-up, a few rare cases of weakening appear. But as a few additional injections invariably correct the condition such weakening can hardly be called recurrence, certainly not in the postoperative sense, where surgery offers only a complete new operation to correct the condition. I myself never consider my own treatments complete without these periodic later examinations and (when needed) reinforcing injections.

It should be clear that I had made special arrangements inviting the return of patients in whom weakening or recurrence might occur and that I therefore had special reason for assuming the hernias gone and forgotten when the patients failed to appear. Obviously too I was fully conscious that patients are prone not to appear when recurrence develops and that end result figures unchecked by careful follow up have no reliability.

There can of course be no objection to his taking exception to my conclusions if his experience and judgment warrant. I

offer no criticisms on his disagreement over the solution I use. He himself, however, employs a phenol and thuja solution which I consider extremely dangerous, as evidenced by the article by Drs. Zieman and Larkowski in THE JOURNAL, Nov. 7, 1936, reporting tissue necrosis resulting from the use of such a solution.

I am also convinced that with wider experience he will find the injection method applicable to virtually all the accessible abdominal hernias, several of which he now contraindicates.

S. W. FOWLER, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DESENSITIZING TO HISTIDINE IN ALLERGY

To the Editor:—A boy, aged 14 months, is allergic, having eczema and gastro-intestinal disturbances consisting of intestinal cramps, gas formation and diarrhea. Although attempts have been made to correct the condition by eliminating the offending foods, it has not been successful, as he is sensitive to many foods and soon is on an insufficient diet. Even then he is not entirely free from symptoms. In some cases of allergy, particularly chronic urticaria, good results have been obtained by desensitizing the patient to histidine, the amino acid which is the decomposition product of any protein. Can you tell me whether any work has been done in desensitizing to histidine in cases such as I have described? If not, why wouldn't this be a rational plan? Would there be any danger with such a procedure in such a young child; that is, any more than in an adult? What dosage would you start with: the same as that used in the adult with chronic urticaria? Please omit name. M.D., Ohio.

ANSWER.—Weiss and Aron (*Presse méd.* 41:1880 [Nov. 22] 1933) attributed the presumed beneficial effect of histidine in peptic ulcer to a replacement factor. They found that when the normal digestive process had been interfered with experimentally in dogs so that protein digestion was incomplete, peptic ulcer developed. This could be relieved with histidine injections and they believed that ulcer was due to a histidine deficiency in the tissues resultant on defective protein digestion.

Lenormand (*Presse méd.* 41:1141 [July 19] 1933) expressed his belief that the beneficial effect of histidine therapy in ulcer was due to its action on the vagus-autonomic system, causing an increased secretion of mucus and thereby protecting the gastric mucosa. Acting on the same theory he employed a mixture of 2 per cent tryptophan and 4 per cent histidine in the therapy of hay fever. Injections were given daily, intracutaneously and in doses of from 0.2 to 0.4 cc. Treatment was given only in the presence of symptoms; that is, coseasonally. Among twenty-nine cases, fourteen were reported entirely relieved, eight much improved and five improved. He attributed this improvement to stimulative action of the intracutaneous inoculation on the vagus-sympathetic system with resulting increased secretion of mucus in the nasal mucosa, which served to protect the mucous membrane against pollen contact. He believes that histidine may be broken down in the skin into histamine, thereby producing a histamine effect.

Lenormand reported that he did not obtain relief in other allergic manifestations such as nonseasonal asthma, food and drug sensitization or migraine.

Israel and Jacob (*Presse méd.* 43:1288, 1935) reported relief from asthma by scarification of the skin and application of 4 per cent histidine hydrochloride to the scratches.

There do not appear to be any reports of unfavorable reactions from the intracutaneous or scratch use of histidine in the concentration recommended. What benefits may accrue appear to be temporary, lasting only through the duration of the treatment.

There is some risk of permanent scarring from the continued intracutaneous injection of such large amounts of fluid.

One American investigator (work unpublished) tied intragluteal injections of histidine in a variety of allergic diseases without evidence of benefit.

It develops from the foregoing that the only method of administration which has been reported beneficial in some allergic

states (hay fever and asthma) has been after intracutaneous administration. It also is apparent that it is a temporary palliative at best and should not be used as a substitute for more effective or more permanent allergic methods when the latter are practicable.

Skin reactions to foods are less reliable than those to inhalants. A positive food reaction does not necessarily mean that the person cannot eat that food. On an average, anywhere up to half of the positively reacting foods may be found to be harmless. It may possibly be found therefore that the diet need not be as rigidly restricted as appears from the tests.

The dose of histidine for a child 14 months of age should be about the same as for an adult, 0.1 or 0.2 cc. intracutaneously. Since no unfavorable reports have been reported, it would appear that there are no contraindications to a trial of this method of treatment.

DIGITALIZATION BY MOUTH AND BY VEIN

To the Editor:—Can you tell me the quantitative difference, if any, in digitalization by mouth and by vein? Assuming that it would take from 20 to 30 cat units to digitalize, is there any valid reason why this could not be done as well, or better, by vein than by mouth—if, say, not more than 2 to 4 cat units is given every three or four hours—of course watching for signs of digitalization. This when none had been given recently. Would it be entirely safe to digitalize by vein, figuring to give half a dose, one fourth in six hours and the remainder in six hours?

L. L. STARKEY, M.D., Harlingen, Texas.

ANSWER.—The difference in dosage between digitalis given by mouth and given by vein is not known with sufficient accuracy to justify the administration of digitalis intravenously except in extreme emergency. Just what such an occasion might be it is hard to say. It would rarely occur, if ever.

A smaller dose is effective if given by vein. Digitalis is standardized to a degree of accuracy quite sufficient for oral administration, but it is not absolutely accurate or constant. Small variations in action would be of much greater consequence if given intravenously.

Digitalis might be administered as stated in the question without any great degree of danger. But it is not devoid of danger to the patient, and why do it?

TREATMENT OF BEGINNING DEMENTIA PARALYTICA

To the Editor:—A white man, aged 35, had dilatation and blurring of vision of the left eye. He had syphilis in September 1925 and was treated by a prominent surgeon in New Orleans, with nearsphenamine, size of dose not known, given at weekly intervals for four injections, and then two more injections one month apart. As the case was diagnosed early at that time by the Wassermann reaction, which he stated was 2 plus, it was thought that the treatment was adequate. After these six injections the Wassermann reaction was negative and has been checked yearly since that time and has always been negative. Examination of the eyes was negative with the exception of a fixed dilated pupil of the left eye about 10 mm. in diameter. Treatment has been 0.3 Gm. of nearsphenamine for two injections and then 0.45 Gm. of nearsphenamine for eight injections for the past ten weeks, together with 30 grains (2 Gm.) of potassium iodide daily. Before treatment was begun, spinal puncture was done with the following results: gold curve 5555543210, Wassermann reaction 4 plus. The left pupil is still dilated to about 7 mm. in the daytime. In bright light the vision is about 20/40. However, after about the fifth treatment the pupil began to react to light and somewhat to accommodation, the improvement in accommodation not being as good as the reaction to light. A complete neurologic examination was made at the start of treatment ten weeks ago, which was negative except for the left pupil and accommodation. However, in the last few days he has been having very slight auditory hallucinations, and while talking to him recently I noticed that he was evidently becoming slightly unbalanced, telling me that his teeth all that day would suddenly protrude toward his lips and that he would have to push them back in line (his teeth are very sound and are widely spaced), saying that his teeth are crowded. What treatment should be pursued at this time? Please omit name and address.

M.D., Indiana.

ANSWER.—The history is unfortunately the history that is so often given by the average patient with syphilis. The doctor, instead of treating the case of syphilis with the required amount of treatment, depends entirely on a Wassermann reaction. As soon as the Wassermann reaction becomes negative, he believes that the syphilis is cured. Unfortunately, this is not the case. The patient would have been far better off if he had had thorough, continuous treatment with arsenicals and bismuth compounds at the time he contracted the disease. By sufficient treatment is meant at least thirty injections of an arsenical and a like amount of an insoluble bismuth salt, for example, bismuth salicylate.

Apparently now he is suffering from a beginning dementia paralytica, which is indicated by the symptoms and by the gold colloid curve, all of it due to lack of adequate treatment. The

patient should have a course of malaria therapy. If he stands it all right, probably taking from twelve to fifteen chills, and following this, if the eyegrounds show no contraction, it would be well to put him on a long course of tryparsamide injections, giving them intravenously once a week, starting off with a dose of 1.5 Gm. and gradually working up to a maximum of 2.5 Gm. Sometimes after the third or fourth injection the patient will complain a little of blurring of the eyes. If this is the case, the treatment should be discontinued for one or two weeks and then cautiously begun again, whereupon there will probably be no difficulty. Often as many as fifty weekly injections of this preparation are given in similar cases.

Naturally, it would be impossible to outline further treatment without information at a later date.

CYCLIC NAUSEA AND VOMITING

To the Editor:—A girl, aged 17 years, complains of severe nausea and vomiting accompanying her menstrual periods. The periods began at 13 years of age. The first six months they were irregular but since that have been regular, the interval being twenty-eight days. The periods last between five and seven days, the flow being normal in every respect. The nausea and vomiting began about two years ago and has been getting progressively worse. The periods begin without the patient's knowledge, there being no prodromal symptoms and no cramps or sickness at onset. Usually between two and four hours after the onset of the flow she begins to feel faint, followed by nausea and vomiting. The stomach is emptied of food, after which she vomits gastric secretions and bile. This continues for about twenty-four hours. The patient is 5 feet 4 inches (163 cm.) tall and weighs 120 pounds (54 Kg.). Physical examination reveals absolutely nothing. Pelvic examination has not been made. As for treatment I have advised in the way of general measures plenty of exercise and sunshine, a well balanced diet, and strict elimination. Internal treatment has been confined to the use of thyroid, from one-half to 1 grain (0.03 to 0.065 Gm.) twice a day for two months, without improvement. Sedatives have been used beginning several days before the expected flow without results. I also tried antuitrin-S, 100 rat units, every three days. This was done only for one month, which I realize was not enough to bring about much change. Do you advise more antuitrin-S and, if so, how much should be given and over how long a period? Would it be advisable to use corpus luteum? Anything you may suggest in the way of treatment will be appreciated. If this should be published, please omit name.

M.D., Nebraska.

ANSWER.—In most instances the cause of the nausea and vomiting that are occasionally associated with the menstrual periods is unknown. Regardless of this, a thorough study of the gastro-intestinal tract, including gastric analysis and the x-rays, should be made in this case to rule out a possible abnormal local condition. Likewise a rectal examination should be made to determine whether the internal genitalia are normal. If any abnormality is detected in the gastro-intestinal tract or the pelvic organs, it should of course be treated. If the investigation of the gastro-intestinal tract fails to reveal any abnormal condition and "the physical examination reveals nothing," the most likely cause of the cyclic nausea and vomiting is a psychic one. The treatment of such a condition is usually difficult. There is no logical reason for giving antuitrin-S, progestin or any other glandular extract to the patient except for its psychic effect.

SENSITIVITY TO PAINTS

To the Editor:—I have been consulted about a man who has been employed in a furniture factory as a painter. He applies the paint with a spray-gun. After he had worked in this factory for two years he developed a dermatitis. This would affect not only the skin but also his eyes, and his lips would swell in addition to the violent dermatitis elsewhere. He would discontinue his work for a short while and the condition would clear up. On his return to work there would be a recurrence of the trouble at varying intervals. This continued for approximately six months or longer and he gave up his work then and began doing something else in which he was not exposed to the fumes of paint. Since then he has had no further trouble. Is there any way in which the cause of this inflammation could be determined: that is, how could it be definitely established that it was due or not due to the paint? Please omit name.

M.D., North Carolina.

ANSWER.—Coating materials are one of the commoner causes of industrial dermatoses. The fact that this workman develops recurrences whenever he reuses paint and is free from involvement when away from the paint constitutes in itself suggestive proof of a cause and effect relationship.

Some substantial proof may be obtained by carrying out patch tests, using the paint as a test material. Various techniques have been recommended for patch test work. A simple procedure is now mentioned: On the flexor surface of the cleaned forearm a single drop of the paint material should be applied, covered with a 1 inch square of two or three layers of gauze and then

with a 2 inch square of rubber damming. The rubber damming should be held in place with adhesive tape, and perhaps a few turns of a bandage should be thrown around the entire area. A control test with a single drop of water or other innocuous material should be applied in similar fashion.

At the end of twenty-four hours an area of clear-cut inflammation at the point of application of the paint suggests the likelihood of responsiveness to that agent. However, in some instances it may be necessary for the patch test to continue in place for ninety-six hours. Conversely, it is true that some paint materials are so irritating that all persons respond before twenty-four hours, not because of sensitiveness but because of the direct irritating properties of the paint.

Should it be desirable to know the exact ingredient within the paint responsible for any positive reaction, a similar patch test may be carried out with individual constituents, for these constituents may be determined through analysis or through information derived from the manufacturer. However, most paints designed for one particular purpose, such as furniture coating, are likely to contain substantially the same ingredients.

ASTIGMATISM

To the Editor:—Can astigmatism of less than 1 diopter result from a blow on the eye, when there are no lacerations of the cornea? I refer to corneal astigmatism. A fellow practitioner states that only astigmatism of several diopters can result from a blunt object striking the eye. In my personal experience I have found several cases in which it was necessary to add a 0.25 or a 0.50 cylinder to lenses after the eye was injured by tennis balls or other objects. What is the incidence of unilateral astigmatism? Please omit name.

M.D., New Hampshire.

ANSWER:—In none of the standard text or reference books can there be found any mention of a low degree of astigmatism resulting from nonpenetrating injury. It is of course conceivable that a blunt injury might cause enough damage to the sclera to result in a scar formation with resultant contraction to produce corneal astigmatism of even a low degree. But an injury of such an extent would leave other visible stigmas. How does the questioner know that the low amount of astigmatism did not exist before the injury? Furthermore, it is well known that such low degrees of astigmatism are apt to be physiologic. Tscherning said "It is rare to find an eye completely free from astigmatism . . . and the limits of physiological astigmatism will vary from 0.5 D to even as high as 1.5 D."

Unilateral regular astigmatism is extremely rare, probably because there are so few nonastigmatic eyes. The numerical incidence is not known.

HAZARD TO EYE FROM ARC WELDER

To the Editor:—A man was exposed to an arc welder at rather close range, the length of a sledge hammer, for six or seven hours at intervals. He wore no goggles. This happened about eight weeks ago. The vision on the first examination was 20/70 in both eyes and he went through the usual external manifestations of an injury of that type with acute conjunctivitis and photophobia. The vision gradually improved to 20/30—2 and has remained stationary. The fundi appeared hyperemic. The disk has shown no pallor. The fundi appear normal at present. Fields taken three weeks after the injury were contracted down to from 10 to 15 degrees from fixation in both eyes. Color fields were contracted to within 5 degrees of fixation. There has been no improvement. Do you think you can give me any information as to whether an injury of this type is capable of producing such a contraction in the fields? What is the prognosis? In the literature I have available, cases are quoted in which there has been permanent injury to the nerve and cotoma, mostly central, but I can find no case in which damage has created a field picture of this nature or as extensive and symmetrical in the two eyes. The Wassermann reaction is negative and the sinuses are normal. Please omit name.

M.D., New York.

ANSWER:—There are no cases recorded in the literature of the end results of exposure to ultraviolet or even infra-red radiation, such as are recorded here. An exposure of the eye to an excess of radiant energy may well result in intra-ocular damage as well as superficial damage, but in such cases the lesions can be seen within three weeks after exposure. Thies reported a case of iritis following repeated exposures. Numerous cases of damage to the macular area of the retina have been reported by Knapp, Vogt, Goldman, Roy and others; but in these cases there has always been a central field defect and eventually a pathologic lesion appeared in the macula. Hypothetical damage to the choroid has been mentioned, but never with peripheral field loss.

The continued contraction of the visual field is highly suggestive of what has been termed traumatic neurosis. In fact, in the earlier days, it was considered pathognomonic. In view

of the lack of any subjective or objective evidence except the visual field contraction, suspicion must be directed toward a probable psychic element.

HOOKWORM IN DOGS

To the Editor:—Several months ago I was presented with a Chesapeake Bay dog, 3 months old, which was brought from the Eastern Shore of Maryland. Instructions were that the dog had been wormed several times and would require worming a few weeks after her arrival here. I was a few weeks late in doing this, and when the dog was wormed was surprised to learn that it was infested with hookworms. Since then the dog has been wormed three times at intervals of two weeks by the veterinarian, who used the carbon tetrachloride treatment, the last report being only a few worms. I also have about the grounds a small toy fox terrier, aged 4 years. To add to this a complicating factor, also on the grounds are three young children. The question is concerning the hookworms. I have knowledge of their habits but would like more definite information as to whether the dog can ever be entirely freed from them and what is the best advice from a health standpoint. If possible I should like to keep the dog, and even if I should get rid of the dog ought the ground receive special attention? I should like authoritative information on this.

A. J. KNAPP, M.D., East Liverpool, Ohio.

ANSWER:—There is no reason why a dog should not be entirely freed from hookworms. The carbon tetrachloride treatment might be supplemented with trichlorethylene or hexylresorcinol. It is entirely possible that the dog's continued infestation represents new infestation continuously acquired during treatment. If this is true, treatment during the winter when the larvae in the contaminated ground are killed will be effective. There is no need to worry about the dog's infestation from a health standpoint. The two common hookworm infestations of dogs are with *Ancylostoma caninum* and *Ancylostoma braziliense*. The latter infestation is of interest in medicine because the larvae from the soil invade the human skin and set up one type of creeping eruption. It is most likely, however, that this dog is infested with *Ancylostoma caninum*, which is as far as is known does not live any length of time in the skin of man and does not set up any disease process other than very transient papules. In any case it is not necessary that the ground should receive any attention and it is probable that in Ohio the winter is severe enough to eliminate the soil infestation.

TREATMENT OF LATENT SYPHILIS

To the Editor:—About four years ago a married white woman, aged 32, took her first-born child to the hospital for examination. A Wassermann blood test was strongly positive and tests made on both parents were likewise positive. Antisyphilitic treatment was begun promptly and continued over a period of about two years, when the child and the father became Wassermann negative. Treatment was discontinued, and subsequent tests have remained negative. Meanwhile another child was born and a blood test was positive. Treatment was instituted and this child likewise improved to the extent that the blood test taken about six months ago was negative. At the same time the mother's test was "doubtful positive." There was a difference in the treatment used with the mother, as arsenicals had to be discontinued after the first course of eight injections and two injections of the second course. Neoarsphenamine was used, I understand. Preparations of bismuth and mercury have been used continuously since, with rest periods, which the patient says were sometimes as long as four weeks between courses. She came to me for the first time five months ago. Because of the history of reactions following the use of arsenic, I felt restrained from trying this drug. I started her using the mercury rubs and iodides by mouth. She reported soon afterward that she had profuse salivation and nasal discharge and also some lacrimation, so these drugs were discontinued. I then began injections of bismuth (bismo-cymol) one injection every five days for nine injections, when a blood test was made, which was "doubtful positive." Another course of eight injections of this drug was carried out; then mercury rubs alone were used without apparent untoward reaction. These were continued daily for two weeks; now I am beginning another course of the bismo-cymol. I would appreciate your opinion relative to further therapy in this case and if, at the conclusion of this course of bismuth when I plan to check again the Wassermann reaction, it is positive (or doubtful positive) still, would it be prudent to try the arsenical drugs? Please omit name.

M.D., California.

ANSWER:—An effort should be made to determine why the mother's Wassermann reaction remains positive. This would necessitate a spinal fluid test and search of the cardiovascular system for evidence of aortitis or aortic regurgitation, as well as examinations for other evidences of visceral manifestations of syphilis. If such careful search fails to elicit any signs of the disease, the patient may then be placed in the group of latent syphilis. The treatment of patients with latent syphilis cannot be systematized in the same manner that the treatment of acute syphilis can be regimented. Accordingly, in the management of these patients, the treatment must be individualized. It would seem advisable to continue the bismuth therapy in this woman if the diagnosis of latent syphilis is justifiable, not

only because of her intolerance to arsphenamine but more especially because bismuth therapy in latent syphilis has resulted in serologic reversal to negative in the majority of the cases when it is given over a long period. The fact that she is still in the child bearing age is another reason for continuing treatment. If the cardiovascular and neurologic examinations, spinal fluid and other examinations are negative, even though on reexamination the Wassermann test of the blood is found to be positive, there is no need of jeopardizing the patient's future by giving her arsphenamine. If, however, the spinal fluid is strongly positive or if she should become pregnant again, small doses of arsphenamine of a brand not previously used might be given if great caution is exercised in its administration.

ETIOLOGY OF SUDDEN FALL IN HEMOGLOBIN

To the Editor:—A woman, aged 39, married, with two children, occasionally has a sudden fall in hemoglobin accompanied by fatigue. These attacks seem directly proportional to worry and fear. The hemoglobin may fall 25 per cent in twenty-four hours under mental stress. There is also a fall in blood pressure from 120/65 to 110/60. There is a slight fall in the red blood cell count, but not so marked. She recovers in a week under iron by mouth and liver intramuscularly. Without this treatment it takes three or four weeks. She has a moderate degree of chronic sinusitis and peribronchial infiltration; otherwise examination is negative. The basal metabolism is normal. Tests are negative for tuberculosis. Until recently I presumed that these attacks were due to hemolytic streptococci activated by fatigue, but now I feel that the picture changes too rapidly to be explained by bacterial invasion. Is it possible that the adrenal gland can be affected by worry and cause this sudden fall in hemoglobin? Any data you can furnish will be appreciated. Please omit name.

M.D., Indiana.

ANSWER.—It is difficult to visualize a situation of such an acute nature in which the drop in hemoglobin level is distinctly greater than that of the red blood cell level. As the actual figures for the latter are not included, one may assume that the percentage drop in the two levels is similar. Acute relapse or exacerbation of hemolytic anemia may be precipitated by worry or fear. Such a state may be recognized by the presence of icterus, increased fragility of the red blood cells to saline solutions and the occurrence of a greater than normal percentage of reticulocytes in the circulating blood. Relapses may be precipitated by worry or fear in patients with pernicious anemia, but these occur seldom so acutely and rarely do the blood levels return to normal without specific treatment. An abrupt drop in the hemoglobin and red blood cell levels may follow an attack of paroxysmal hemoglobinuria, which is, however, precipitated by exposure to cold. A positive Wassermann reaction is almost invariably present in the blood serum of a person so afflicted. Such a condition as that described cannot be accounted for on the basis of an altered function of the adrenal gland.

FLOCCULATION TEST FOR PREGNANCY

To the Editor:—Please describe the method of pregnancy determination by means of the ninhydrin flocculation test. How reliable is it? Please omit name.

M.D., Illinois.

ANSWER.—The ninhydrin test of pregnancy is based on the theory that the body reacts to the presence of foreign proteins by producing specific proteolytic ferments to destroy them. It is thus similar to the anaphylaxis reaction.

The occurrence of a reaction is indicated by the formation of diffusible products of protein hydrolysis, which may be detected with a substance called ninhydrin (triketohydrindene hydrate). Ninhydrin reacts with any alpha-amino acid, giving a blue or violet color. Or the change in optical rotation that occurs in a solution of peptone under the hydrolytic action of the serum may be observed.

Although this test was introduced by Abderhalden as a method of diagnosing pregnancy on the assumption that the chorionic cells of the placenta enter the maternal circulation and cause the formation of specific defensive ferments, it is known today that the test is not specific. The diagnostic value of the test for either clinical or scientific purposes must be considered as unproved. The protease activity of the serum seems to be increased in pregnancy, but simply shaking normal serum with kaolin or other foreign substances may cause it to give a strong reaction with placental antigen.

With the discovery and perfection of the Aschheim-Zondek test of pregnancy, which has an accuracy of about 98 per cent in pregnancy, hydatid mole and chorionepithelioma, there is no longer any need for experimentation with complicated and uncertain tests such as the ninhydrin test.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, May 1, page 1564.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral examinations for Group A and B applicants* will be held in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Practical examination* will be given at Philadelphia in June. *Written examination* will be held in different centers of the United States and Canada in October. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 7 and Chicago, Oct. 9. *All applications and case reports, in duplicate, must be filed at least sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Atlantic City, N. J., June 8. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Philadelphia, June 7-8. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Mich.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Philadelphia, June 2. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Oral examination.* Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Colorado January Report

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held in Denver, Jan. 6-8, 1937. The examination covered 8 subjects and included 170 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Nine physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Texas School of Medicine.....		(1936)	87
Osteopath *			87

School	LICENSED BY ENDORSEMENT	Year Grad. of
University of Arkansas School of Medicine.....		(1930) Arkansas
Yale University School of Medicine.....		(1934) N. B. M. Ex.
George Washington University School of Medicine.....		(1911) Dist. Colum.

Book Notices

The Medical Value of Psychoanalysis. By Franz Alexander, M.D. Second edition. Cloth. Price, \$3. Pp. 278. New York: W. W. Norton & Company, Inc., 1936.

This book represents an attempt by Dr. Franz Alexander to "place psychoanalysis among the sciences." It is a well written book, stating in clear fashion the concepts which make up what Alexander chooses to call the "science of psychoanalysis." That the neurotic individual must learn to accept repressed psychologic facts, while the psychotic must learn to accept rejected external facts, constitutes one of his main theses. This is undoubtedly true, but certainly analysis is of no therapeutic avail in the treatment of the psychoses, and even in the treatment of the neuroses there is no scientific data by which to indicate analysis as the method of choice. One can accept his idea of the autonomic nervous system as a development serving to relieve the central nervous system of a portion of its work. This division of labor copes with the two fundamental problems of the organism, orientation in the external world and regulation of inner metabolic processes. The central nervous system relieved of its task of inner regulation thereby becomes more efficient in solving problems in external reality. Entire independence of the autonomic from the central nervous system cannot however be realized in the human body. There is a complicated interrelation between the two, which Alexander feels, properly enough, may be acted on by psychic as well as by organic stimuli.

The author's brief references to the psychoanalytic investigations of organic disease are interesting, although one may object to the suggestion that one's symptoms prove one's retreat to an infantile level of oral receptiveness and aggressiveness. No modern physician, whether he agrees with Alexander or not, will deny the psychogenic factor in the causation of many organic conditions, and since the author himself admits to a probable underlying constitutional or biologic defect in those cases which go on to the development of organic changes, even the strictest of the organicists can find no serious quarrel with him on that score. One can, however, quarrel with the limited approach of psychoanalysis, even to a determination of only the psychogenic factors of disease; life phenomena cannot all be fitted into so little or so rigid a framework.

Alexander suggests that psychoanalysis might be taught in the medical schools, although it should not have a place of dominance in the course of psychiatry. Freud has greatly added to knowledge and philosophy. His therapeutic contribution seems to lie mainly in the realm of technic.

This book by its simplicity of language tears away much of the mysticism with which analysis has surrounded itself—a good move. It makes the stand of the analyst clear and invites intelligent criticism, of which, no doubt, there will be and should be much.

Grundlagen einer neuen Therapieform der Tuberkulose. Von Dr. Med. Wilhelm Pfaff, Leiter der TBC-Therapieforschungsabteilung des Krankenhauses Tönsholde der L. V. A. Schleswig-Holstein, und Dr.-Ing. Willy Herold, physikochemiker, wissenschaftlicher Mitarbeiter. Paper. Price, 17.80 marks. Pp. 249, with 135 illustrations. Leipzig: Georg Thieme, 1937.

Although great strides have been made in the treatment of tuberculosis by the various methods of collapse therapy, there are a great number of cases, unfortunately, in which collapse therapy cannot be satisfactorily induced. With this in mind, the authors reconsidered the possibility of some other method of therapy whereby some form of medication could be administered which, by reaching the tuberculous focus through the blood stream, directly or indirectly, could favorably affect the tuberculous infection. To be effective, such a medicament must be able to reach the tuberculous focus. In view of the previous conception of the tuberculous focus as being an avascular structure, the writers conducted a series of experiments to verify or negate this conception. It is of the results of these experiments that this book treats. The first part of the book, by Pfaff, contains an excellent description of the anatomy and physiology of the lung, with particular reference to the anatomy and physiology of the capillary system. The modern views

concerning inflammatory reactions and responses both tuberculous and nontuberculous are gone into in detail with authoritative references. A section on allergic responses is included. Particular attention is given to the rôle of the reticulo-endothelial system. The second part of the book, by Pfaff and Herold, deals with their investigations on the mesenteries and lungs of living dogs. Both the normal and inflammatory, specific and nonspecific conditions were studied. The third part of the book, by Pfaff, describes several other research problems of a similar nature. The writers believe that they have satisfactorily established the fact that various dyes reach the tuberculous focus when injected in the blood stream and that the tuberculous structure is not an avascular one. They therefore believe that if a specific therapeutic agent can be found it can reach the tuberculous focus through the blood stream and can be used to overcome the tuberculous disease. They invite the development of such an agent.

Be Glad You're Neurotic. By Louis E. Bisch, M.D., Ph.D. Cloth. Price, \$2. Pp. 201. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1936.

It is unfortunate that one who has had the training in psychology and psychiatry which the author of the present volume has apparently had would permit himself to turn out such a volume. It is an extremely superficial rehash of the most elementary material on neuroses, psychoses and freudian mechanisms. The definitions are loose and in many places meaningless. The book scarcely deserves serious review. It consists of a number of chapters exhortative in their nature, each urging the individual to be glad that he is neurotic and to assure him that if he has guilt feelings, if he has bad dreams or insomnia, if he feels that he is going insane, he has nothing to worry about. The author gives the impression that the neurotic is anybody who is above normal in intelligence, whereas numerous neurotics are subnormal. He states baldly that a psychopath is one who is suffering from emotional inadequacy, not instability, and yet a large class of psychopaths examined in any clinic are the unstable psychopaths. He generalizes, for instance, in saying that the courts do not recognize the diagnosis of psychopath, whereas in most large cities this is not true. Specific examples of this sort of loose, unscientific and misleading information could be carried on endlessly. Toward the end of the book he has a chapter on glands, written in the best "Berman" fashion. It is a general, superficial discussion of glandular balance and imbalance, stressing the fact that the glands can be made useful or not as the individual desires. Before concluding the volume the author gives a test for an individual to give to himself to see whether he is neurotic. A person who is or is not neurotic, who gives himself this test, is bound to find some ideas that will disturb him. The real neurotic who might read this book, give himself the test and try to act out the principles involved would probably find himself in deep difficulties. Since it is a well known fact to psychiatrists that lectures embodying simple encouragement and simple exhortation are of little value, since most neuroses and mental difficulties are of deeper origin than the subject himself knows, this book must be pointless. Bisch concludes with a set of five rules: "Study yourself," "Stop reproaching yourself," "Be proud of what you are," "Turn your handicaps into assets," "Profit by your neurosis," "Be glad," which all in all make one compare the book to a football coach talking between the halves to a losing team that has been much outplayed and outweighed.

Wills Hospital Eye Manual for Nurses. By Gladys Elaine Cole, R.N., Chief Nurse, Wills Hospital, Philadelphia. Cloth. Price, \$1.75. Pp. 202, with 97 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This booklet, by the chief nurse of Wills Eye Hospital, is just what the title says, a manual for nurses written in simple language without too many technicalities. On the whole, it is well done and contains much easily accessible valuable information. Particularly to be commended are the lists of surgical procedures with the instruments required for each and the proper methods of sterilization. Of course, each ophthalmic surgeon and each ophthalmic institute has its own technic, so that many of the minor points will be disputed. The illustrations, which are copied from various sources with due credit,

are not particularly good and could be elaborated and improved on to great advantage. Seven pages are given to an outline of the history of cataract operations, abstracted from Posey and Brown's book, which appears superfluous in a manual of this type. But there is a good glossary at the end, just before the complete index. The booklet is valuable for nurses in the special field of ophthalmology and the efforts of the authoress are to be highly commended.

Il glutathione: Sua importanza nella biologia generale e nella fisiopatologia umana. Dal Dott. Giuseppe Barbaro-Forleo, aiuto dell'Istituto di patologia speciale medica nella R. Università di Pavia. Prefazione del Prof. Luigi Zoja, direttore della clinica medica della R. Università di Milano. Paper. Price, 30 lire. Pp. 448. Pavia: Tipografia già cooperativa, 1936.

The contents of this monograph are divided as follows: (1) structure and biologic significance of glutathione; (2) glutathione content of organs and tissues of living organisms, and its variations under physiologic and pathologic conditions; (3) histochemical reactions of glutathione and methods for its indirect determination in tissues and biologic fluids. The second part is by far the most extensive. It gives a complete survey of the field of the occurrence of the tripeptide under physiologic and pathologic conditions. A complete bibliography brings this useful book to a close. On the whole, the monograph does not represent a mere compilation of literature references; the vast material has been treated with a full appreciation of the problems involved and with fine critical acumen aided by the author's rich experimental experience in the field. It is to be regretted that the book is so far available only in the Italian original, which fact might restrict its use among research workers for linguistic reasons. It is to be hoped that an English translation will soon be forthcoming.

Recent Advances in Radiology. By Peter Kerley, M.D., B.Ch., D.M.R.E., Assistant Radiologist, Westminster Hospital, London. Second edition. Cloth. Price, \$5. Pp. 322, with 178 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

The author's effort to keep this volume abreast of the advances in radiology has been successfully carried out in that the work really represents what its name implies. Extensive alterations and additions to the chapter on bone diseases have taken account of the remarkable advances in calcium metabolism and endocrine diseases as reflected in roentgenograms. Enlargements have been made in the chapters on the skull, the gastro-intestinal tract and the lungs. The chapters on the heart, the biliary tract and the renal tract have been entirely rewritten. Of necessity in a work of this size there is much condensation, but all the important radiologic advances are described. The illustrations have been increased by seventy new contributions; some of the old ones have been replaced by better and more characteristic specimens. As a record of the recent advances in radiology this book can be recommended.

The Diagnosis and Treatment of Chronic Diseases of the Respiratory Tract, with Especial Reference to the Lesions of the Trachea, Bronchi, Lungs, Pleura and Diaphragm. By Elmer H. Funk, M.D., Physician to the White Haven Sanatorium, Philadelphia. Revised by Burgess Gordon, M.D., Medical Director and Physician-in-Charge, Department of Diseases of Chest, Jefferson Hospital, Philadelphia. Henry A. Christian, M.D., Sc.D., LL.D., General Editor of the Series. [Reprinted from Oxford Monographs on Diagnosis and Treatment.] Cloth. Price, \$8. Pp. 618, with 182 illustrations. New York: Oxford University Press, 1936.

This volume is a reprint from Oxford Monographs for 1929. It was written by the late Dr. Funk, clinical professor of medicine at Jefferson Medical College, and revised by Dr. Gordon. The book is divided into four parts: general considerations in the diagnosis and treatment of diseases of the lower respiratory tract (eighty-nine pages), diseases of the trachea, bronchi and lungs (250 pages), diseases of the pleura (eighty-two pages) and pulmonary tuberculosis, new growths, and diseases of the diaphragm (179 pages). It is unfortunate that the revision still contains the old references to the literature used in the Oxford Monograph for 1929. In the entire book there are only nine references to publications on diseases of the respiratory tract later than 1929. As an illustration of the failure of the references to keep abreast of the times it is noted that on page 255 a footnote on pneumoconiosis (silicosis) mentions "the recent monograph on pneumoconiosis (silicosis) by

H. K. Pancoast and E. P. Pendergrass (P. B. Hoeber, Inc. New York, 1926)." The same criticism applies to the chapter on pulmonary new growths and most of the other subjects. Also the text needs to be brought down to date in many of the chapters. On page 425 appears the statement "The present conception of the pathogenesis of tuberculosis indicates that every individual under the ordinary conditions of our civilization is infected soon after birth." Recent investigations indicate that only about 30 to 40 per cent of grammar school and college students have a primary complex of tuberculosis. Let us hope that in the next edition the numerous developments of the past eight years will be included. The book is well printed in large type and has many excellent illustrations.

The Emancipist: An Historical Drama. In Three Acts. By Maj.-Gen. John Macquarie Antill, C.B., C.M.G., and his daughter, Rose Antill-de Warren. Cloth. Price, 3s. 6d. Pp. 165. Sydney: Angus & Robertson, Ltd., 1936.

The chief medical interest of this volume lies in the fact that Dr. William Redfern, surgeon in the navy, convict, and friend of Macquarie, is portrayed as its hero. His arrest and conviction on the basis of sympathy for mutineers, his arrival in Sydney in 1803, and his development as leading surgeon in the colony make him an interesting medical historical character. A note indicates that this is the first Australian historical play to be published in book form.

Gestes et procédés techniques de chirurgie générale. Par Jean Berger, chirurgien des hôpitaux de Paris. Paper. Price, 32 francs. Pp. 137, with 124 illustrations. Paris: Masson & Cie, 1936.

In this little volume Berger has made a commendable effort, by word and illustration, to convey the manual movements and general procedures of surgery to the mind of the beginner. It is difficult to feel much enthusiasm for a work of this type. The surgical intern will learn these procedures in the operating room at the elbow of an accomplished surgeon far more accurately and far more quickly than he can hope to by perusal of a book. The illustrations, while instructive, are of second grade. Perhaps the best chapter is the third, in which the author lists the qualifications of an expert surgeon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Harrison Narcotic Act: Prescribing for Addicts.—The city of Los Angeles established a clinic wherein narcotic addicts whose addiction had become pathologic could, after being examined by physicians and certified, receive a quantity of narcotics. Subsequently the clinic was closed and the defendant, a physician, was requested by the city health officer "to take over the prescribing for these addicts who had been certified by the clinic." For this service the defendant was compensated by the city. After several months during which the defendant prescribed for clinic patients, indictments were returned against him and a druggist charging, in effect, that they in violation of the Harrison Narcotic Act sold and dispensed unlawfully certain quantities of morphine sulfate not in good faith and not in the course of their professional practice. The indictments were dismissed as to the druggist, and the case against the defendant was heard before the United States district court, southern district, California, central division, without a jury. The indictments charged specifically that the defendant during a period of approximately seven weeks prescribed 2,489 one-half grain tablets of morphine sulfate for three former clinic patients, and that during the same period he prescribed 1,233 one-half grain tablets of morphine sulfate for a nonclinic addict, all not in good faith and not in the course of professional practice.

The constitutionality of the Harrison Narcotic Act, said the court, has been upheld on several occasions solely on the ground that it is a revenue measure. If it should be subject to the

construction that it regulates either the sale of narcotics within a state or the practice of medicine, its constitutionality could not be upheld. *Linder v. United States*, 268 U. S. 5, 45 S. Ct. 446; *United States v. Doremus*, 249 U. S. 86, 39 S. Ct. 214; *Nigro v. United States*, 276 U. S. 332, 48 S. Ct. 388. The Linder case, continued the court, laid down the rule that the act does not attempt to limit the quantity of narcotics a physician may prescribe for an addict. Furthermore, in *Strader v. United States*, 72 F. (2d) 589, the United States circuit court of appeals, tenth circuit, said in reference to the Harrison Narcotic Act:

The statute does not prescribe the diseases for which morphine may be supplied. Regulation 85 issued under its provisions forbids the giving of a prescription to an addict or habitual user of narcotics, not in the course of professional treatment, but for the purpose of providing him with a sufficient quantity to keep him comfortable by maintaining his customary use. Neither the statute nor the regulation precludes a physician from giving an addict a moderate amount of drugs in order to relieve a condition incident to addiction, if the physician acts in good faith and in accord with fair medical standards.

The act, continued the court, does not regulate the frequency of prescriptions nor does it require that dispensing by physicians be limited to an immediate need. It does not forbid a physician to give to a patient a large prescription for self administration under certain circumstances—warranted either by impossibility of hospitalizing the patient, or other conditions, or by the desire to continue him at his work. The courts have laid down no dogmatic rule to determine what is good or bad professional practice. That must be established by the same rule by which the courts determine whether malpractice exists in a certain case. The law punishes not bad judgment in a physician but bad faith. Circumstances may arise where, from the unexplained number of prescriptions, the unlimited amount, and the relationship of the parties, an inference of bad faith might be drawn without any other evidence. The law does not compel such a conclusion, however, to be drawn in all cases in which the prescription is not limited to one dosage or several dosages. Where there is an explanation, the court must determine whether or not there was good faith, in the light of the expert testimony, of the testimony of the defendant-physician himself, and of all the circumstances in the case.

The evidence in the present case, the court pointed out, did not show the case of a physician who, looking for gain, sought to capitalize his knowledge by preying on unfortunate addicts. It was undisputed that the city health officer asked the defendant to take over the work of the clinic and that he was paid by the city. Under such circumstances, the court thought, to find that the defendant violated the law merely because the law enforcement authorities thought he was not so careful as he might have been with reexaminations and in issuing drugs to persons who in their opinion should have been hospitalized would do violence to the very spirit of the law. This does not mean, the court said, that a person might not be guilty of an offense under the act although he followed the advice of the city medical authorities. Such officials cannot give absolution for criminal offenses any more than can law enforcement officers, by placing their own interpretation on the law, create an offense which does not exist. A physician is not punishable under the Harrison Narcotic Act, however, unless the evidence indicates bad faith and a failure to follow accepted medical practices. The court thought that too much attention had been given in the case to the fact that the chief of police of Los Angeles stated that under no circumstances could prescriptions be issued to the clinic addicts without reexaminations, and that the local narcotic agent made a similar statement. Neither the chief of police nor the federal authorities, the court said, can dictate to a physician the manner in which he may treat patients. There was expert medical testimony to the effect that the treatment administered by the defendant was proper under the circumstances and conformed to the high professional ideal of the Hippocratic Oath. This oath, the court said, makes it the duty of a physician to relieve suffering and to use his own judgment in doing so. He should not be punished when he lives up to it.

For the reasons stated, the court found the defendant not guilty of any of the offenses with which he was charged.—*United States v. Anthony*, 15 F. Supp. 553.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Atrisia of Pylorus. R. J. Bennett Jr., Edmonton, Alta.—p. 44.

Blood Pressure Changes During Defecation.—During 1931 Klinefelter attended six patients who died suddenly from cerebral hemorrhage while they were attempting to move their bowels. Since then he has examined more than 300 male patients by measuring their blood pressures during defecation. A significant rise in blood pressure was observed. With a corresponding degree of stress, this rise averaged 20/15. But the greater the degree of stress, the higher the rise in blood pressure. In one patient this effort produced an increase amounting to 110/88. Certainly an increase in blood pressure such as this would appear to add considerably toward the danger of rupture of the wall of a diseased blood vessel. Examination of patients affected with different diseases revealed nothing specific; the blood pressure changes did not differ markedly from the average. Alterations of blood pressure in disease seemed different only so far as the disease interfered with the ability to strain.

Relation Between the Oral and the Gastric Flora.—Hood and Arnold classify the organisms from cultures of the mouth and stomach and determine the relation which these bear to one another. They observed the effect of continuous entrance of the exogenous flora and studied the protective mechanism by which the body defends itself against this entrance. Cultures from the mouth and stomach show a striking similarity in bacterial flora. This must mean that the oral flora is present in the stomach either as a transient or as an established inhabitant. Although these micro-organisms which are continually washed into the stomach are nonpathogenic for the most part, there is always the possibility of introducing a virulent type. *Bacillus coli* was found in only three of twenty-five gastric aspirations. Even in these cases the salivary flora was present in greater concentration than were the coli types. By means of a test organism it was found that bacteria may remain active in the oral cavity for three and one-half hours after contact with the mucosa and structures within the cavity. This gives a long period during which organisms are continuously passed into the stomach. Thus if pathogenic bacteria have been the contaminants there will be not only the

original infecting material for disinfection by the gastric juice but also this smaller but continuous inoculation over a long period during which time there may be fluctuations in the gastric acidity. Simultaneous cultures made from the contents of the mouth and stomach showed that the average disappearance rate of test organisms from the mouth was two and one-half hours and from the stomach one and one-fourth hours. Any diminution in the number of bacteria was brought about as readily by rinsing the mouth with physiologic solution of sodium chloride as with a disinfectant. Evidently the diminution in the numbers of bacteria is due to the mechanical washing away of organisms rather than to the disinfecting powder of the fluid itself. Although saliva contains many micro-organisms, the bacterial flora of the stomach was not noticeably influenced by diverting the flow of saliva from the stomach for a period of two hours.

Connective Tissue Reaction in Multiple Sclerosis.—In every one of his thirteen cases of multiple sclerosis, King found networks of argyrophil connective tissue fibers growing diffusely into the parenchyma. The extent of this growth varied from case to case and even from plaque to plaque. In part the reticulin nets grew from blood vessels of small caliber, predominantly capillaries and precapillaries; in part they appeared to grow independently of preexisting reticulin. Diffuse reticulin invasion may be one of the early pathologic reactions in multiple sclerosis and is found not only in the white matter but in the cerebral cortex and other gray masses. The growths appear to be definitely related to the disintegration of myelin, with the intensity of the process playing some part. Such reticulin nets bear no correlation with the degree of gliosis, of axis cylinder destruction or of perivascular infiltration. This type of connective tissue proliferation takes place independently of fibroblasts. Eleven cases of diffuse sclerosis studied can be divided into three groups, of which the first showed no reticulin nets, the second a slight or moderate growth rather similar to that in multiple sclerosis and the third a profound growth, showing qualitative as well as quantitative differences from that in multiple sclerosis. The term diffuse sclerosis does not represent a unitary condition.

Essential Immunizing Antigen of Typhoid Bacillus.—Felton and Wakeman's study confirms the earlier results of Douglas and Fleming that the fat-free dried cells are apparently superior to liquid vaccine. Several explanations of this finding suggest themselves: (1) that the method of preparation of a liquid vaccine may decrease some of its activity, (2) that the lipoids present may actually retard or inhibit the development of the active component and (3) that there may be some other product developed during the growth of the bacilli which in some manner paralyzes the immunizing mechanism. In this preliminary report tests were made only on fractions of the cell that may be considered polysaccharide in nature. It would appear that the essential immunizing antigen was present in all samples studied, but in varying amounts. The fractions low in nitrogen content and high in dextrose number were the strongest in active immunizing power. From the fact that, when alkali was used during the process of isolation, all fractions were weakly if at all antigenic (active immunity) it would appear that there may be both active and inactive forms of this fraction of the typhoid organism. In other words, strong alkali destroys the immunizing capacity. However, it is not to be inferred that this alteration necessarily follows the saponification of any acetyl groups present in the molecule. It is concluded that at least for mice there is an essential active immunizing antigenic fraction of the typhoid organism. This organism may therefore be added to the list of organisms which may be so fractionated, namely pneumococcus, aertrycke as found by Boivin, Mesrobian and Mesrobian and later by Raistrick and Topley, and Brucella, from which Pennell and Huddleson reported the isolation of a crystalline b-anthraquinone carboxylic acid which exhibits an active antigenicity.

Genesis of Thyroid Protein.—Salter and Lerman discuss the action of iodine in the hyperthyroid animal or patient from the standpoint of the chemical effect that it produces in the gland itself. The administration of iodine in hyperthyroidism must produce a profound disturbance in the manufacture of hormone. The effect of iodine therapy is intimately related to the genesis of thyroid protein. The most striking histologic effect resulting from the administration of iodine to a patient with exophthalmic goiter is the rapid filling up of the follicles with newly formed colloid. As a result of this phenomenon the clinician feels the gland becoming smaller and harder in

the course of a few days. Coincidentally, the histologist finds that many of the follicles have become spheroidal and so filled with eosinophilic material that they might be mistaken at first sight for normal thyroid or colloid goiter tissue. At the same time the biochemist is able to demonstrate a rapid accumulation of iodine within the gland, which may increase the iodine content tenfold or more. Thus, both chemical and microscopic studies emphasize the appearance of new-born thyroid protein. Given elementary iodine and the ordinary constituents of protein, the organism is able to manufacture thyroglobulin at a rapid rate. Of the various factors involved in this complicated process, the action of enzymes is most important. In order to simulate the natural production of thyroid protein, it would be ideal to start with elementary iodine and simple amino acids. Diiodotyrosine peptone was the substance used as the starting point in the artificial production of thyroid protein. It would be proper also to use for this purpose an enzymic preparation derived exclusively from thyroid tissue. The principle is one of reversible reaction in accordance with the mass law. An enzyme, being merely a catalyst, facilitates the progress of a reversible chemical reaction in either direction. The actual course in any given instance is determined by such conditions as concentration, solubility and temperature. The formed product was an albuminous substance, which resembled natural thyroglobulin in many respects. In terms of iodine, the yields varied from 15 to 40 per cent of the original starting material. The chemical properties of this artificial protein are similar to those of natural thyroglobulin. Actual curves presenting the rise in the basal metabolic rate of individual patients with myxedema when fed this artificial protein show an average daily rise in metabolism of 2.6 per cent.

Cerebellar Abscess, with Diffused Suppurative Labyrinthitis.—Fernando and de Ocampo report a case of otogenic cerebellar abscess with recovery. The patient was admitted with symptoms definitely pointing to labyrinthine disturbance. The hearing and caloric tests showed that the labyrinth was completely irresponsive; but also there were phenomena which could not be explained by this condition alone. The direction of the nystagmus, which was toward the diseased ear and which was not to be expected in a destroyed labyrinth, the continuous headache and insomnia and the mode of falling made the authors suspect some intracranial involvement besides the diffuse suppurative labyrinthitis. This was strengthened by the presence of slight rigidity of the neck on the day before operation, which prompted the lumbar puncture that showed serous meningitis. The meningitis was more or less of the irritative or protective variety. So their suspicions were narrowed down to a localized intracranial suppuration, more specifically an abscess of the temporal lobe or the cerebellum. Symptoms and signs of involvement of the temporal lobe (left side) were lacking. The presence of cerebellar abscess was then quite evident, and on the morning of the operation (Newman-Jansen endocranial technic) additional though vague localizing symptoms appeared in the form of weakness of the grip of the left hand and adiadokokinesia. When labyrinthitis and cerebellar abscess occur together the symptoms are confusing. The patient was kept in the hospital for almost four months. Maximal drainage and minimal traumatism were

assured by cautious insertion of a rubber drain. The pus obtained from the abscess was sterile, probably owing to the disintegration of the bacteria by some unfavorable tissue reaction. The route of infection must have been through the labyrinth. Lumbar puncture made three months after operation revealed normal spinal fluid, showing that the patient had recovered completely from the otogenic serous meningitis.

Caution in the Use of Protamine Insulin.—In discussing the reactions from the use of protamine insulin, Jordan mentions that of the seventeen patients treated unconsciousness occurred in six and in three instances the duration of the reaction was far longer after the initiation of treatment for the hypoglycemia than is usually true with regular insulin. Although carelessness in carrying out the advised treatment led to these severe reactions in four of these patients, the errors were glaring in only two instances, and in four of the six cases mild reactions occurred at similar times even when directions were followed. These hypoglycemic reactions have been troublesome almost entirely in the cases being tried on a single daily injection of protamine insulin alone. Enough protamine insulin to take care of the three meals is usually too much for the fasting period during the night. For this reason the author has prescribed a bedtime lunch and the taking of the breakfast fruit as soon as the patient awakes in the morning. In other cases this has been insufficient, and reduction of the amount of protamine insulin was necessary. To compensate for this the injection of a few units of regular insulin just prior to breakfast was made. Local reactions with redness, swelling, pain and tenderness at the site of injection have occurred in several cases. Occasionally a patient will be unable to take food, owing to nausea, vomiting or unconsciousness occurring shortly after the injection of the new insulin. It then becomes necessary to supply food repeatedly throughout the day and night by artificial routes. Indiscriminate use of protamine insulin should be avoided because of its powerful and prolonged action.

Treatment of Minor Burns by Amyl Salicylate.—Stewart discusses the results in thirty-nine cases of minor burns treated with amyl salicylate blended with a liquid mixture of isomeric methyl tertiary butyl phenol, 1:1,000 of the 5 per cent phenol solution. This produced a stable analgesic and antiseptic solution. The burns were of third degree in five patients and of second degree in the remainder. The patients presented themselves at the hospital within a few hours after injury; in eleven instances, however, they did not come until one or more days had elapsed, and there was therefore potential or actual sepsis present from the outset of hospital treatment. There is a direct relationship between the depth of the lesion, the presence of sepsis and the length of time required for treatment. The results were almost uniformly good. Healing progressed steadily, and it was seldom that any of the patients complained of really appreciable discomfort. Especially when the primary surface dressing remained intact and there was no excessive exudation, the treatment was painless throughout. The resulting scars were smooth and pliable, though some showed a little surface scaling, which soon disappeared. No contractures occurred. Prompt healing was obtained in a number of cases in which there was some degree of initial sepsis. Amyl salicylate lacks the coagulant effect of tannic acid on the tissues and is therefore unsuited to the treatment of severe and extensive burns from which there is a danger of toxemia and shock. The ester has little if any bactericidal power and therefore requires the addition of the antiseptic. The method is applicable to the treatment of infected as well as noninfected burns and scalds, provided the initial infection is not too severe. When the patients present themselves the affected area is cleansed with physiologic solution of sodium chloride and all raised epithelium is removed. Swabs soaked in amyl salicylate and the antiseptic phenol solution are applied directly to the area, those in actual contact with the raw surface being only two or three layers of gauze in thickness. Wool and a bandage are then adjusted. The patient subsequently attends at intervals of four days, when, if possible, only the outer swabs are removed and the thin one next to the lesion is left in place. Fresh outer swabs, wrung out of the solution, are applied after any excess of serous discharge has been wiped away. As the burnt area dries up and epithelium grows over it the lowest or primary gauze layer loosens off and, when it completely separates, the lesion is found to be healed. Under such conditions the patient has no pain, and no cutaneous irritation or erythema has so far been observed. In some instances, owing to a more active exudation, such an ideal technic is impossible, and the entire dressing requires to be changed once or oftener. On occasion there is some scaling or even crusting after the main part of the surface has healed, and olive oil is applied until the scales or crusts separate. Otherwise simple dry gauze dressings are used to protect the recently healed area for a few days.

Arresting Migraine Crises—In 1934 Villey and Buvat presented three cases of epilepsy in which regular intravenous injections of hypertonic salt solutions were given. The favorable results obtained led them to attempt these injections against migraine. Although the number of cases under observation was small, the results obtained are of interest, as it is known that certain migraines may be regarded as a form of epilepsy. It is a syndrome of intracranial hypertension: headache, vomiting and bradycardia. In the first case there had been violent migraine attacks for several years often lasting for forty-eight hours and refractory to analgesics. An intravenous injection of 20 cc. of a 10 per cent solution of sodium chloride was given: fifteen minutes later the patient began to have a salty taste in her mouth and she soon felt a progressive cessation of pain. Nine days later another crisis was treated similarly and was followed by total arrest of pain. Two other cases of varying severity were treated in the same manner with equal results. But in one patient there was a short lipothymic reaction with a retrosternal sensation of heat. A fourth patient showed no favorable results.

Measurement of Capillary Resistance to Suction of Skin—Recchia and Signorelli studied the value of the tests of resistance of the capillaries to suction of the skin in the clinical diagnosis of actual and latent hemorrhagic diathesis. Suction of the skin was made by a cupping glass. Capillaroscopy was simultaneously performed. The suction test is more sensitive than the bandage test. It shows latent hemorrhage when the latter gives negative or slightly positive results. For interpretation of results the skin suction is made in a given area for four minutes with a decompression of 7 or 8 cu. mm. of mercury. Under the same conditions of time and decompression, the nonappearance of punctiform hemorrhages or the appearance of one or two hemorrhagic points indicates negative results of the test. The appearance of four or five hemorrhagic points shows weak positive reaction, that of from six to ten hemorrhagic points indicates average positive results, and more than ten hemorrhagic points indicates intense positive results of the test. Besides the number of hemorrhagic points, the diameter and morphology of the induced hemorrhages (combined capillaroscopy) and the rapidity of appearance and volume of the cutaneous hemorrhages have to be evaluated.

Treatment of Puerperal Fever—González's management of puerperal infection consists in absolute abstinence from any intravaginal examination, intra-uterine lavage or any local application of medicine. The treatment consists only in rest and administration of drugs which stimulate the natural defenses

of the organism. The treatment is based on the theories of immunity, the diapedesis phenomenon and the local defensive action of the leukocytes if they are not disturbed. The author has obtained satisfactory results from the treatment since 1919 in several maternity hospitals of Argentina, and his results have been reported to medical congresses. Since this treatment was established in Argentine hospitals the prognosis of puerperal fever has entirely changed for the better.

*Constitution, Race and Tuberculosis: Anthropologic Studies on One Thousand Patients with Tuberculosis. F. Potthoff.—p. 180.

Primary Tuberculous Complexes in Mesenterium—Oesterreich, in studying the necropsy material of the pathologic institute of the University of Greifswald, observed that in this material the primary tuberculous process was in the mesenterium more frequently than occurs in other necropsy materials. She emphasizes that the most frequent source of infection of primary intestinal tuberculosis is the milk of tuberculous cows. In view of this fact, she thinks that the high incidence of primary mesenteric complexes in the necropsy material of Greifswald may readily be explained. This material is derived largely from rural regions in which the people habitually consume raw milk, usually from their own cows, the milk being neither pasteurized nor subjected to control as regards the tuberculous infection of the cows.

Constitution, Race and Tuberculosis—Potthoff subjected 1,000 men with tuberculosis to careful anthropologic studies. He was unable to detect a particular shape of the thorax among these men and he also failed to detect the so-called paralytic shape of the thorax. On the contrary, he found not only that the chest measurements of the tuberculous patients corresponded to the average of the population but that there was even a comparatively large percentage in whom the chest measurements exceeded the normal. Investigations on the relationship between racial characteristics and tuberculosis revealed no connection between these factors. The largest part of the report takes up the problem of constitution, but here too the author arrives at practically the same conclusion as in the other two questions. He found that the extremely asthenic body structure is just as rare among the tuberculous patients as among the population in general. In the conclusion he emphasizes that there is no special externally recognizable and anthropologically measurable constitutional structure that is characteristic for tuberculous patients or indicates a predisposition for tuberculosis.

Investigations on Size of Ossification Nuclei in Wrist in Normal Children Aged from 5 to 15 months, with Especial Regard to Diagnosis of Myxedema. Grete Gørtz and S. Gørtz.—p. 43.

Tuberculous Splenomegaly and Splenogenic Inhibition of Bone Marrow Function—Engelbreth-Holm reports four cases of tuberculous splenomegaly. He says that splenomegaly on a tuberculous basis can lead to inhibition of the bone marrow function and thus occasion certain changes in the peripheral blood, among which anemia and leukopenia are most common and thrombopenia is less common. Examinations of the bone marrow seem to indicate that these changes in the blood depend on a restriction of the maturing or sending out of blood cells from the bone marrow and not on a restriction of cell production in the bone marrow.
